Abstract:

Leading societies toward a more sustainable, equitably shared, and environmentally just future requires elevating and strengthening conversations on the non-material and perhaps unquantifiable values of non-human nature to humanity. Many of the sustainability solutions proposed by scientists and decision-makers are based on a human-centered perspective that put at risk non-utilitarian aspects of ecosystems and species. Our essay explores the wide global diversity of perspectives on the human-nature relationship and argues that our best chance for effective conservation is to take a pluralistic approach that engages seriously with the worldviews of all stakeholders. We also highlight how many worldviews—particularly those in many indigenous cultures—place a higher value on the spiritual and non-material aspects than what is often represented by the discourse surrounding Western conservation policy. We discuss how alternative framings of human-nature relationships that recognize nature's intrinsic value can be powerful motivators for social change and for local-scale conservation efforts. At a national and international level, changing ethical framings of our relationship with nature have already started influencing our conceptions of human rights relating to the environment and of the rights of nature itself; this has led to an increased role of the judiciary in promoting environmental sustainability and in promoting justice for those groups who are most often affected by environmental harms. It is our hope that this essay will motivate the scientific community to change its own perception of what a sound and sustainable relationship between humanity and other species should be and will help citizens become active environmental subjects, connected to the ecosystems around them.

2 **Abstract**

3 Leading societies toward a more sustainable, equitably shared, and environmentally just future
4 requires elevating and strengthening conversations on the non-material and perhaps unquantifiable
5 values of non-human nature to humanity. Many of the sustainability solutions proposed by
6 scientists and decision-makers are based on a human-centered perspective that put at risk non-
7 utilitarian aspects of ecosystems and species. Our essay explores the wide global diversity of
8 perspectives on the human-nature relationship and argues that our best chance for effective
9 conservation is to take a pluralistic approach that engages seriously with the worldviews of all
10 stakeholders. We also highlight how many worldviews—particularly those in many indigenous
11 cultures—place a higher value on the spiritual and non-material aspects than what is often
12 represented by the discourse surrounding Western conservation policy. We discuss how alternative
13 framings of human-nature relationships that recognize nature’s intrinsic value can be powerful
14 motivators for social change and for local-scale conservation efforts. At a national and
15 international level, changing ethical framings of our relationship with nature have already started
16 influencing our conceptions of human rights relating to the environment and of the rights of nature
17 itself; this has led to an increased role of the judiciary in promoting environmental sustainability
18 and in promoting justice for those groups who are most often affected by environmental harms. It
19 is our hope that this essay will motivate the scientific community to change its own perception of
20 what a sound and sustainable relationship between humanity and other species should be and will
21 help citizens become active environmental subjects, connected to the ecosystems around them.

1. Introduction

As the 21st century progresses, humanity faces an increasingly crowded, hotter, and more degraded planet, creating an urgent need to reevaluate our relationship with the natural world. Despite decades of international multidisciplinary scholarship, global biodiversity and climate conventions, and concerted efforts by policymakers, human impact on the Earth's natural systems has become unsustainable across a wide range of metrics (Steffen et al. 2015). We contend that to preserve the species and ecosystems that humanity has interacted with and depended on for millennia, scientists, government officials, decision makers, and society at large must all deepen and expand their understanding of diverse ways human societies relate to and interact with non-human nature.

Conservation is a global endeavor and is by definition a multicultural project. The international conservation discourse has often been dominated by a set of worldviews that originated in Western societies; this has in many cases been an obstacle to its success. The worldviews and ethical constructs that scientists and society bring to problems of environmental sustainability determine how situations are perceived, how problems are framed (Figure 1), and what solutions are preferred or simply considered. The worldviews that presently dominate the international discourse on sustainability—in particular ecosystem services and related frameworks—have emerged out of a materialistic worldview that has taken a primarily anthropocentric perspective (Descola 2013). These perspectives lead humans to undervalue nature, in particular the multitude of non-material dimensions of the human-nature relationship, which can in turn influence the practice of ecosystem management and restoration (Machaqueiro & Grinker 2019).

Our essay argues that effective conservation requires practitioners to study more deeply the diverse ways that societies conceive the human-nature relationship and to put these conceptions and perspectives on an equal footing to those that have historically dominated the conservation discourse (Brondizio et al. 2016). An additional benefit of studying diverse alternative worldviews is that it will likely improve our understanding of what constitutes a good life and will provide new and alternative approaches to addressing environmental problems. The rest of our essay is organized as follows. We first discuss the necessity of viewing conservation as multicultural project and the significance of cultural difference in conservation. We next discuss the importance of non-material values across cultures which creates an inherent weakness for conservation approaches based on ecosystems services. We conclude with an agenda for the future that highlights the recent global emergence of the judiciary as a powerful means to obtain more rapid and effective conservation actions.

2. Motivating conservation on a multicultural planet

While global efforts to conserve species and ecosystems have not kept up with the pace and scale of global environmental change (WWF 2018), successful conservation actions have occurred and continue to occur across the globe. The success of those efforts is often determined by the degree to which they align with local cultural conventions and worldviews; techniques that work in one locale may find limited success elsewhere.

To take one particularly prominent example, the nature as service provider framework—including the concept of ecosystem services (ES) and associated programs such as payments for ecosystem services (PES)—has been successful in driving conservation efforts in many locales, for example, wolf conservation in the Northwest of the United States and in Finland where compensation

payments to ranchers have been a central part of conservation efforts (Muhly & Musiani 2009; Hiedanpää et al. 2016). Another example comes from Switzerland, where the Landscape Quality Contribution program (Contribution à la qualité du paysage), which provides payments to promote aspects of landscape quality such as increased biodiversity and reduced erosion, expanded in the three years following its 2014 launch to the point where it was working with three quarters of farmers in the country (OFAG 2017). However, in many contexts these efforts have fallen short of expectations. This may partly be due to a phenomenon called motivation crowding: financial incentives may crowd out pre-existing motivations for pro-environmental behavior because they can promote a shift in the way people relate to their environment (Frey & Jegen 2001). In addition to motivation crowding, a broader obstacle facing PES schemes in some areas is that the idea of nature as commodity implied by PES can itself be at odds with the worldviews of some stakeholders whose support these programs need to succeed (Winthrop 2014).

On what could be considered the opposite end of the spectrum from the valuation and compensation approach taken by PES programs, globally there are growing efforts where nonmaterial aspects of nature as well as spiritual beliefs regarding nature take center stage in motivating conservation efforts. For example, La Via Campesina, an international farmers' organization created in 1993 supporting peasant empowerment and promoting sustainable alternatives to large-scale agriculture, shows that alternative movements can be motivated in part by a non-materialistic perspective on human well-being that is based on community integrity and on respect for human and natural balance (Kohler & Negrão 2018; Caraway 2018). More broadly, small farmers and indigenous movements have worked to restore traditional knowledge, improve gender equality, promote virtuous environmental practices through agroecology, and enable

87 peasant empowerment (Perfecto et al. 2010; Altieri & Toledo 2011). In all of these cases,
88 underlying motivation has no connection to financial incentives.

89 Sacred sites—present on every inhabited continent—are frequently a powerful motivator of
90 conservation (Dudley et al. 2009) and illustrate the diverse and important role that local belief
91 systems can play in driving nature conservation. Sacred sites have motivated conservation efforts
92 in areas as ecologically and politically diverse as tropical forests in southwestern China (Xu et al.
93 2005), broadleaved and dry forests in several Indian states (Chandrashekara & Sankar 1998;
94 Bhagwat & Rutte 2006), montane systems in the Ecuadorian (Carter & Sarmiento 2011) and
95 Chilean (Herrmann 2006) Andes, riverine ecosystems in Siberia (Klubnikin et al. 2000), boreal
96 forest in Canada's western arctic (Gill et al. 2014), and the high desert of the western United States
97 (Stoffle et al. 2017). Sacred natural sites are often community focal points with specific ecosystem
98 features having particular significance, for example in spiritual ceremonies (Jeeva et al. 2006;
99 Ormsby & Ismail 2015). The psychological and spiritual well-being of individuals and
100 communities is often linked to knowledge of the existence and integrity of sacred sites, meaning
101 that the degradation of these sites can represent an important spiritual loss to individuals (Russell
102 et al. 2013). Sacred sites can in some cases be so inextricably linked to cultural identity itself that
103 the loss of a site can result in a significant change to a society's identity (Garibaldi & Turner 2004;
104 Vitebsky 2015).

105 Even in the absence of traditional sacred sites, or in cultures where such sites do not exist, a sense
106 of connection to place can nonetheless be an important motivator for conservation (Windsor &
107 McVey 2005). This can be seen in the motivation of support for national parks (Weiler & Moore
108 2013), or in the manner that an appeal to cultural tradition has been effective at motivating
109 conservation of working landscapes in countries across Europe (Fischer et al. 2012).

These examples emphasize that effective conservation actions require the support of diverse stakeholders who invariably perceive the world differently and have different sets of motivations. The path to success lies in finding strategies that work for the worldviews and motivations of the different stakeholders involved in any given project or location—not all strategies work in all contexts. Improving our understanding of the diverse ways that people globally conceive of the human-nature relationship, and in parallel, according those different conceptions the same respect that we give our own, is an essential step to successful conservation.

3. Seeing the human-nature relationship differently

The diverse approaches to conservation described above succeeded in part because they were well-aligned with the worldviews of the stakeholders whose buy-in and support mattered. While the number of potential perspectives on the human-nature relationship is limitless, there are nonetheless some common themes of difference that can be seen when we study the human worldviews. In particular, the degree to which nature and humans are seen as separate as well as the degree to which nature is considered to have intrinsic value as opposed to value that derives from its utility to humans.

Considering intrinsic value means according a value to other species or ecosystem components that is separate from the question of whether or not any human is benefited by their existence (Davidson 2013). Considering intrinsic value means that non-human species are seen as ends in themselves and not simply as means to benefit human well-being; it suggests that other species have a right to exist that is independent of any consideration by humans (Taylor 1986; Rolston 1989; Batavia & Nelson 2017). The question of intrinsic value has figured prominently in critiques of conservation approaches that assign a monetary value to ecosystem services (Kumar & Kumar

2008; Wegner & Pascual 2011). Although the effort to value ecosystem services is primarily a tool for analyzing trade-offs and do not necessarily preclude a consideration of intrinsic value (Costanza et al. 2017), it is nevertheless important to remain conscious of the degree to which the framing of an approach—and the degree to which that framing is consistent with the worldviews of stakeholders—matters when it comes to project success.

Findings from the environmental social sciences illustrate several areas where an economic valuation of ecosystems can conflict with the worldviews of relevant stakeholders; in particular, (i) in many cultures, the concepts of “nature as service provider”, “ownership of nature”, and simply “nature” as an entity that is separate from humanity are foreign and objectionable; (ii) many aspects of the human connection with nature are unquantifiable and are not amenable to trade-offs with any kind of material benefit; (iii) many environmental practices are highly social in nature, rendering inadequate the notion of an economic exchange among individuals as a basis for evaluating those practices; and finally, (iv) many cultures and individuals consider nature to have intrinsic value apart from any utilitarian value (Winthrop 2014).

Many Indigenous and local peoples’ concepts of human-nature relationships are based on a sense of spiritual, non-materialistic connection. These cosmologies and spiritualities of Indigenous peoples and other groups are anchored in specific territorial contexts and offer alternative worldviews and frameworks for guiding relationships between humans and the rest of nature (Kealiikanakaoleohailani & Giardina 2016; Descola 2013). In many indigenous cultures, human societies and the environment are perceived not as separate, but rather as involved in a unique relationship (Berkes 2012) that embraces both spiritual and symbolic values (Caillon et al. 2017). Generally, worldviews based on indigenous experience have more completely internalized the idea that humans are living organisms among many others and that we depend on the rest of nature for

our own survival (Saxena et al. 2018). These worldviews have helped many indigenous and local people to sustainably manage their environment for decades or centuries (Johnson et al. 2016).

Among worldviews that provide a model for the human-nature relationship, animism deserves special attention. The first understanding and description of animism was basically that of a religion attributing a soul to both animate and inanimate objects. The definition has since evolved to embrace the so-called “shamanic complex”, a worldview mainly found in Siberia, North-Eastern America, South America, and among several aboriginal peoples of South-Eastern Asia (Descola 2013). Animism has been considered the antithesis of Naturalism, the Western worldview that considers humans (Culture) separate from Nature—the rest of the living beings. Animist spiritualities are based on the idea that “humanity” does not characterize or constitute a species (ours), but rather is a condition of existence shared among all living beings. In contrast to Naturalism and the associated Nature-Culture dichotomy, animism is based on the idea that all living beings share the same culture, while their bodies differ according to their ecological behavior (Viveiros de Castro 2015). In animist worldviews, living beings—humans and all others—engage with each other in social relationships that include exchange, reciprocity, predation, and even sexual relations. special rights to humans above other beings (Descola 2013).

Spiritual or emotional bonding with nature is not unique to animist cultures. The importance of place and sense of place in maintaining human well-being in both indigenous and non-indigenous cultures is documented in a rich and diverse literature (Windsor & McVey 2005 and references therein). Whether it be termed “place attachment,” “settlement identity,” “homelands,” or “landscape of home,” a sense of place provides individuals and groups with a sense of belonging, of security, and of control (Windsor & McVey 2005). These perspectives are not immutable but can in fact be promoted: time spent interacting with nature leads many individuals to report a sense

178 of belonging and spiritual fulfilment, or a sense of the presence of something greater (Vorkinn &
179 Riese 2001). This spiritual connection—which has been shown to be relatively independent of an
180 individual's belief system—can result in emotional or spiritual harm being experienced by
181 individuals in response to degradation of natural areas (Cunsolo Willox et al. 2012). On the
182 positive side, these connections can lead to individuals taking greater responsibility for the
183 conservation and integrity of natural places (Heintzman 2003, 2012).

184 4. An agenda for culturally-responsive conservation

185 To be effective, conservation policies and programs need to take a pluralistic approach and
186 recognize cultural differences in what motivates people in their relationship with nature.
187 Conservation that takes seriously all worldviews and all perspectives on the human-nature
188 relationship is strategic, practical, and ethical. It is strategic because it will improve program buy-
189 in; practical because it increases the likelihood that practitioners will identify locally-appropriate
190 approaches; and ethical because it commits to the inclusion of views that too frequently are
191 marginalized. Conservation programs and policies will see greater success if they invest in
192 understanding local worldviews and if they give a place at the table to stakeholders with diverse
193 worldviews. In recent decades, conceptions of nature as service provider have perhaps taken an
194 oversized role as the guiding worldview in policy discussions around conservation, particularly at
195 the international level. Recently, the concept of nature's contributions to people (NCP) has
196 provided an alternative to ecosystem services (ES) that provides an avenue where cultural
197 differences are considered in the valuation of what nature provides to humanity (Diaz et al. 2018);
198 however, NCP nonetheless retains the ES focus on benefits to humans. A more holistic approach
199 to conservation—that we argue would be a more effective approach—would in particular provide

more space for worldviews that recognize the intrinsic value or the inherent rights of nature. A recognition of the rights of nature would be particularly impactful in its influence on national and international jurisprudence.

The recently-completed IPBES Land Degradation and Restoration Assessment (IPBES 2018) contends that the scientific community, government officials, decision-makers, and civil society need to move beyond a narrative of nature as a commodity in order to better understand how individuals and societies conceive their relationship with nature and how those relationships with nature affect human well-being in both material and nonmaterial ways. A richer engagement with diverse worldviews and perspectives on human-nature connection can guide the development of policy and management options that more effectively avoid and reverse environmental degradation. We also believe that there is an urgent need to reconnect citizens with Nature. Alternative but potentially universal concepts of human-nature relationships have already begun to diffuse into societies in a variety of ways. At a global level, the concept of “environmentality” (Agrawal 2005) acknowledges the rise of “environmental subjects”: people who no longer accept remaining passive while the global environment is threatened (Fletcher 2010). At the national level, other alternative concepts can be found in the Constitution of Ecuador (2008) and in Bolivia (Law No. 071, of Mother Earth Rights, and Law No. 300, the Framework Law of Mother Earth and Integral Development for Living Well) which have integrated the concept of “Buen vivir” or “Vivir bien” in order to recognize that individuals depend on nature. These concepts regard land as a living territory with multiple dimensions—both material and immaterial—and define human societal well-being not only in terms of work and material consumption, but instead in terms of social connection, community ties, and harmony with nature (Acosta 2008; Walsh 2010).

222 Movements such as La Via Campesina and new legal frameworks such as those in Ecuador and
223 Bolivia show that it is possible to shift from a worldview where land is perceived as a commodity
224 to another where social organization is based on an ethic of natural balance as a condition for living
225 a good life. A growing number of global consumers are knowledgeable and supportive of efforts
226 to realign our relationship with the natural world and alter their consumption patterns accordingly.
227 However, even with radical changes to consumption patterns, citizens acting individually will not
228 be sufficient to shift human society to a more sustainable relationship with nature. In many
229 countries, the judiciary is playing an increasingly important role as a tool for citizens to influence
230 policy and decision-makers (Banda & Fulton 2017). A recent report by the United Nations
231 Environment Program documented nearly 900 legal cases initiated worldwide that raise issues of
232 law or fact relating to climate change; to date, the majority of these have related to claims of
233 insufficient government efforts in reducing greenhouse gas emissions (UNEP 2017). Among the
234 most prominent of these is the *Juliana vs. United States* suit, the complainants of which are 21
235 children and teenagers supported by the NGO Our Children's Trust. The *Juliana* complaint asserts
236 that because of its lack of sufficient action to mitigate emissions, the US Government has violated
237 the complainants' constitutional rights to life, liberty, and property and has also violated the federal
238 public trust doctrine (Blumm & Wood 2017).

239 Litigation related to climate change and to other aspects of the environment has often sought to
240 broaden our conceptions of what rights humans have. For example, in many countries, courts are
241 becoming more receptive to the idea that citizens have a right to a stable climate system and to
242 safety from harm resulting from climate change and that citizens may seek legal redress if those
243 rights are violated (Peel & Osofsky 2018). As an example, the circuit court judge in the *Juliana*
244 *vs. USA* suit wrote in a decision that "the right to a climate system capable of sustaining human

life is fundamental to a free and ordered society” (Juliana v. United States, sec III-A). Additionally, climate litigation has in some cases sought to broaden our conceptions of who—among humans—can claim these rights. Future generations, and the duty of care that the present generation owes them, are increasingly referenced in litigation such as *Juliana* (Blumm & Wood 2017). A particularly important development in the legal standing of future generations came in the case of *Rabab Ali v. Pakistan* when the Pakistani Supreme Court allowed a climate change lawsuit to proceed that specifically identified future generations as a claimant (Banda & Fulton 2017). Courts have long played a role in ensuring protection for marginalized groups, and this has consistently been the case when it comes to environmental justice; there are abundant examples of individuals and groups successfully using the courts to protect indigenous rights to lands, to limit industrial pollution, and to reduce other environmental harms (Osofsky 2005).

As much as these lawsuits are ground-breaking in many ways, they nonetheless remain grounded in a worldview where the only rights being considered are those of humans—even if the humans being considered are individuals who are yet to be born. The risk of reliance on such an anthropocentric vision of humanity's relationship with the natural world is that it is not sufficiently balanced by moral or ethical principles that would provide an alternate means of respect and protection for non-human components of nature, including individual animals (Braverman 2018). As Claude Lévi-Strauss puts it: “If man possesses rights as a living being, then it follows immediately that these recognized rights of humanity as a species will encounter their natural limits in the rights of other species. Thus, the rights of mankind stop whenever and wherever their exercise imperils the existence of other species” (Lévi-Strauss 1985: 282). Lévi-Strauss advocated for a “well-conceived humanism” that would leave space on the planet to other species. Considering the interests of non-humans and allowing them to evolve and adapt would be an

268 important step in a more inclusive human ethic and a first step to acknowledging nature's intrinsic
269 value (Burdon 2011). From these new principles could derive new laws framing a new
270 conservation ethic and legal framing for a renewed ecological governance (Wooley 2014;
271 Kauffman & Martin 2018).

272 Indeed, there are examples where the rights of non-human species and of nature generally have
273 already been codified in law. This includes the adoption by the New Zealand Parliament of an Act
274 by which Te Urewera National Park became not simply a park but also a legal entity with "all the
275 rights, powers, duties, and liabilities of a legal person (Ruru 2014); the Colombian Supreme Court
276 of Justice instructing the Government to take action to halt and reverse the degradation of the
277 Amazon forest because of the intrinsic right of the forest to exist (García Pachón 2018). These
278 laws codify the idea that the environment should be defended for its own sake and that have
279 acknowledged both the spiritual and intrinsic values of nature (Knauß 2018). In some cases, the
280 shift to these laws that enshrine the rights of nature have been supported by conceptions of the
281 rights of nature that are products of or influenced by non-western cosmologies (Kauffman &
282 Martin 2018).

283 "Ecological solidarity," an emerging concept in France, could provide a broad-reaching legal
284 framework for the recognition of the inherent value of nature as well as the recognition of the
285 ethical duties that humans have towards nature and towards future generations. As a legal
286 principle, ecological solidarity relies on the existence of moral relationships between humans and
287 non-humans. This kind of coupling is very similar to the spiritual dimension of the
288 human/environment relationship in some indigenous societies and especially that relationship as
289 it is framed by animist worldviews. Originally conceived as a way to consider biological
290 connections around protected areas, it now conveys a more global message based on the

straightforward idea that humans are part of their environment. Ecological solidarity operates on three dimensions: it recognizes the planetary-scale interconnections of ecosystems and ecological process, it encourages intergovernmental negotiations based on global and mutual solidarity, and it promotes a moral framing that emphasizes the common fate of humankind and all living beings (Thompson et al. 2011; Mathevet et al. 2018). Establishing this principle in more countries around the world would more broadly establish the idea that our current generation owes a duty of care to future generations and to other species, requiring legislators, judges, and other actors of the law to take into account the long-term consequences of their actions on nature and future generations. By focusing on the relationship that humans have with the rest of nature (Mathevet et al. 2018), ecological solidarity is a framework that is inherently adaptable to diverse ways of defining what that relationship is.

While the spiritual and ethical worldviews held by individuals are beyond the reach of a policy or a legal framework, we believe that research and outreach—especially in increasing humanity’s contact with nature and in increasing engagement with worldviews that value nature’s non-material and intrinsic values—would create conditions where more sustainable concepts of human-nature relationships can emerge: concepts that emphasize values of cooperation and solidarity over competition and reduce the degree to which high levels of consumption are seen as a symbol of a successful life. Alternative concepts already exist, with more adherents each year, that are based on a moral economy (Edelman 2005). This economy values social relations, limited and local consumption, respect, and solidarity, and is inspired by traditional populations and practices. Its aim is to consolidate social cohesion through community mutual aid and sustainable production-consumption systems (Lebel & Lorek 2008; Tukker et al. 2008). A pluralistic approach to environmental stewardship—one that engages seriously with diverse conceptions of the human-

314 nature relationship—is our best chance to motivate and to lead societies toward a more sustainable,
315 equitably shared, and environmentally just future.

For review only

Figure 1: Perceptions are organized into a hierarchy of concepts dependent on collective systems of knowledge, norms, values and beliefs. These concepts in turn guide cultural, governance and land management practices, as well as resource use and consumer behaviors. Taken together, these elements constitute a worldview. When dominant or mainstream worldviews lead to undesired impact on reality, i.e. the natural world, promoting alternative perceptions and concepts may transform practices towards more desired impacts (Kohler et al. 2018).
