(Received 27 February 2023; revised 20 June 2023; accepted 29 June 2023; published 19 July 2023)
Three three-quasiparticle isomers, one at an excitation energy of 2.3 MeV with $T_{1 / 2}=0.48$ (4) $\mu \mathrm{s}$, and two shorter-lived with unknown half-lives at slightly lower energies have been identified in ${ }^{129} \mathrm{Nd}$ using the MARA + JUROGAM 3 setup and the recoil tagging technique. All three isomers present decay patterns characteristic of high- $K$ isomers. The known $6.7 \mathrm{~s} \beta$-decaying isomer previously assigned to the $5 / 2^{+}$level is now assigned to the new $7 / 2^{-}$ground state. A new low-spin $5 / 2^{+}$isomeric state with a half-life of a few tens of nanoseconds has been identified, while a previously known $2.6 \mathrm{~s} \beta$-decay activity was assigned to the band head of the $\nu 1 / 2^{+}[411]$ band. The transitions depopulating the high- $K$ isomers to low-lying states also establish the relative energies of three low-lying one-quasiparticle bands, leading to a new spin-parity assignment of $7 / 2^{-}$to the ground state of ${ }^{129} \mathrm{Nd}$. The partial half-lives of the depopulating transitions suggest spin-parities $21 / 2^{+}, 19 / 2^{+}$, and $17 / 2^{+}$for the three high- $K$ isomers. The properties of the band built on the $21 / 2^{+}$isomeric state suggest a one neutron-two proton configuration. Based on the results of extensive calculations with different models, we also assign one neutron-two proton configurations to the $19 / 2^{+}$and $17 / 2^{+}$isomeric states. The assigned configurations of the $17 / 2^{+}$and $21 / 2^{+}$isomeric states involve the $\pi 9 / 2^{+}$[404] orbital, which is identified in three-quasiparticle bands of proton-rich $A \approx 130$ nuclei.

[^0]
## I. INTRODUCTION

Exploring and extending the nuclear chart towards the limits of stability is one of the main endeavors in nuclear

[^1]structure. Experiments devoted to the study of extremely proton-rich nuclei by employing radioactive and stable-ion beams, as well as powerful setups composed of recoil mass spectrometers or projectile fragment separators, with highefficiency arrays for detection of $\gamma$ rays and charged particles at the entrance and at the focal plane of the spectrometers. A wide field of investigation remains yet unexplored with stable projectile-target combinations using newly developed instruments which have much higher sensitivity. Such studies with stable-ion beams have been recently performed with the MARA + JUROGAM 3 setup [1-3] in the $A \approx 120$ mass region, revealing extremely rich band structures in the light ${ }^{119,120} \mathrm{Ba}$ and ${ }^{118,119} \mathrm{Cs}$ nuclei, and phenomena unexpected in this mass region, like shape coexistence, chiral bands, or octupole correlations [4-9].

The present experiment, devoted to the study of nuclei with $Z>56$, reports the discovery of three high- $K$ isomers, one low-spin isomer, and a new spin-parity assignment to the ground state in ${ }^{129} \mathrm{Nd}$. From the comparison of the experimental data with configuration-constrained potential energy surfaces (CC-PES) [10], projected shell model (PSM) [11], and particle number conserving cranked shell model (PNCCSM) [12] calculations, we assign one neutron-two proton configurations to the high-spin isomers, two of them involving the $\pi 9 / 2^{+}$[404] orbital. These are the first reported multiquasiparticle high- $K$ isomers involving the $\pi 9 / 2$ [404] orbital in $A \approx 130$ nuclei, which previously were only observed in one-quasiparticle bands close to the ground state of odd-even and odd-odd nuclei like the neighboring $\operatorname{Pr}$ nuclei (see, e.g., [13]), and in odd-even nuclei just above the $Z=50$ closed shell [[14-21]. No high- $K$ isomers are known in the wellstudied Nd nuclei with $N \leqslant 73$ [22-27], while high- $K$ isomers with spins $8^{-}$and $7^{-}$built on two-neutron configurations are known in $N=74$ and $N=72$ isotopes, respectively (see, e.g., [28]). The ${ }^{129} \mathrm{Nd}$ nucleus was previously investigated using the ${ }^{92} \mathrm{Mo}\left({ }^{40} \mathrm{Ca}, \alpha 2 p n\right)$ fusion-evaporation reaction [29] and the $\beta$ decay of ${ }^{129} \mathrm{Pm}$ [30]. Four rotational structures observed up to very high spin have been identified in Ref. [29], and configurations have been assigned based on the measured $B(M 1) / B(E 2)$ ratios, aligned angular momenta, band crossings and signature splitting, and cranked shell model calculations. A 2.3 s isomer was identified by bombarding a ${ }^{96} \mathrm{Ru}$ target with a ${ }^{36} \mathrm{Ar}$ beam and using helium-jet fast tape transport system to measure the $\beta$ decay of ${ }^{129} \mathrm{Pm}$ [30].

## II. EXPERIMENTAL DETAILS AND RESULTS

In the present work, highly excited ${ }^{129} \mathrm{Nd}$ nuclei have been produced using the ${ }^{58} \mathrm{Ni}\left({ }^{78} \mathrm{Kr}, \alpha 2 p n\right)$ fusion-evaporation reaction. The ${ }^{78} \mathrm{Kr}$ beam was provided by the K130 Cyclotron at the University of Jyväskylä, Finland. The target was a $750 \mu \mathrm{~g} / \mathrm{cm}^{2}$ thick self-supporting foil of enriched ${ }^{58} \mathrm{Ni}$. Two experiments have been performed. One without JUROGAM 3 to search for $\beta$-delayed proton emitters, lasting for 10 d with several beam energies between 340 MeV and 370 MeV , and a second one lasting 4 d , in which JUROGAM 3 was added and the beam energy of 364 MeV was optimized for the production of ${ }^{129} \mathrm{Nd}$. The in-flight double-focusing recoil mass separator MARA [1,31] was tuned for mass 133 for
the low beam energies (half of the beam time), allowing the observation of mass 129 which fully overlapped with mass 133 due to an $A / q$ ambiguity. The flight time of the recoils from target to the implantation point is $\approx 450 \mathrm{~ns}$. At the target position, the particle detector array JYUTube consisting of 96 separate scintillator detectors with SiPM (silicon photomultiplier) readouts was used for charged particle identification. In the second experiment in which the beam energy of 364 MeV was optimized for ${ }^{129} \mathrm{Nd}$, the MARA separator was tuned for mass 129 , with the aim to search for the prompt $\gamma$ rays which feed the isomeric states in ${ }^{129} \mathrm{Nd}$ using the recoil gated isomer tagging technique. Prompt $\gamma$ rays were detected at the target position using the JUROGAM 3 germanium-detector array consisting of 24 Euroball clover [32] and 15 Eurogam Phase I-type [33] escape-suppressed detectors, with an efficiency of $\approx 5 \%$ at 1.3 MeV . The clover detectors were arranged symmetrically relative to a plane perpendicular to the beam direction (12 at $75.5^{\circ}$ and 12 at $104.5^{\circ}$ ), while the Phase I detectors were placed at backward angles with respect to the beam direction (five at $157.6^{\circ}$ and ten at $133.6^{\circ}$ ). JYUtube was not in use.

The fusion-evaporation residues were separated as a function of $A / q$ and identified using the MARA separator. At the focal plane a position-sensitive multiwire-proportional counter (MWPC) was used to obtain $A / q$ spectra. Part of the time a double-mass slit system was used to allow only two charge states of a given mass to be transported into the implantation detector, a $300 \mu \mathrm{~m}$ thick double-sided-silicon-strip detector (DSSD) placed 40 cm behind the MWPC. Behind the DSSD a second layer of silicon detectors ( $500 \mu \mathrm{~m}$ thick) is used to veto punch-through events. The time of flight (ToF) between the MWPC and DSSD is recorded. The ToF and the recoil energy deposited in the DSSD were used to distinguish between fusion recoils and scattered beam. Five clover germanium detectors surrounding the MARA focal-plane detection system were used to detect $\gamma$ rays emitted from long-lived isomeric states and daughters of the $\beta$ decays of the implanted recoils. All detector signals were recorded by the triggerless total data readout (TDR) data acquisition system, and time stamped by a global 100 MHz clock, which allowed the establishment of both temporal and spatial correlations between recoils and events obtained with the remaining detectors of the focal plane and of the JUROGAM 3 arrays [2,34].

The data were sorted into coincidence $\gamma \gamma$ matrices and $\gamma \gamma \gamma$ cubes, and analyzed using the GRAIN [35] and RADWARE [36,37] packages. In the first part of the analysis new delayed transitions in coincidence with low-lying transitions already known in the one-quasiparticle bands of ${ }^{129} \mathrm{Nd}$ were identified at the focal plane. Then in the second part, $\gamma-$, and recoil-gated prompt spectra measured in JUROGAM 3 were constructed to identify transitions above the isomers. The multipolarities and the mixing ratios of the newly identified $\gamma$-ray transitions were established based on angular correlations data.

Figure 1 shows a partial level scheme of ${ }^{129} \mathrm{Nd}$, with the previously known bands [29] drawn in black, and the new transitions drawn in red. Three high- $K$ isomeric states have been identified, with excitation energies of 1893, 2109, and 2284 keV , and spin-parity assignments of $17 / 2^{+}, 19 / 2^{+}$, and $21 / 2^{+}$, respectively, discussed in the following. The prompt-delayed $\gamma \gamma$ coincidence spectrum of Fig. 2, obtained

FIG. 1. Partial level scheme of ${ }^{129} \mathrm{Nd}$ showing the isomer and its decay towards the low-lying states. The new transitions are drawn in red, while transitions reported in the previous work of Zeidan et al. [29] are indicated in black. The levels with isomeric character are drawn with thick lines. Excited levels in Band 1 up to energies similar to the highest ones observed in Band 5 are included for comparison. The Nilsson configurations assigned to the bands in Ref. [29] are also indicated. The insert shows a zoom of the low-spin part of Bands 3 and 4.
by gating on the $848-\mathrm{keV}$ transition depopulating the 2284$\mathrm{keV}, 21 / 2^{+}$state and on the $551-\mathrm{keV}$ transition of Band 4 detected at the MARA focal plane, shows a series of prompt transitions which have been grouped in the newly observed Band 5. Spectra of delayed transitions measured at the MARA focal plane, obtained by gating on transitions depopulating the $21 / 2^{+}$isomeric state and presenting transitions in the lower part of the known one-quasiparticle bands are shown in Fig. 3. A singles $\gamma$-ray spectrum, and a projection of the $\gamma \gamma$ matrix measured with the germanium detectors at the focal plane of the MARA separator are shown in Fig. 4. They give an overall view of the relative intensity of the transitions depopulating the isomers, with the $848-\mathrm{keV}$ transition being the strongest. Figure 5 shows two focal plane spectra obtained from the
$\gamma \gamma$ matrix by gating on the $175-$ and $391-\mathrm{keV}$ transitions which depopulate the $21 / 2^{+}$isomer to the lower-lying $19 / 2^{+}$ and $17 / 2^{+}$isomers, respectively. The nonobservation of the transitions depopulating the $17 / 2^{+}$isomer in the spectrum gated by the $175-\mathrm{keV}$ transition indicates the missing $216-\mathrm{keV}$ connecting transition between the $19 / 2^{+}$and $17 / 2^{+}$isomers, giving thus support to the assignment of very different configurations to the two isomers.

The experimental information on the transitions depopulating the three high- $K$ isomers is given in Table I.

The half-life of the $21 / 2^{+}$isomeric state has been extracted from the summed time spectra between the DSSD and the germanium detectors at the focal plane of MARA, by gating on the strong and clean 848 - and $551-\mathrm{keV}$ transitions. A value of

1183.5
${ }^{\text {a }}$ The uncertainty on the transition energies is 0.2 keV for transitions below 1000 keV , and 0.5 keV for transitions above 1000 keV , except when indicated differently.
${ }^{\mathrm{b}}$ Relative intensities corrected for efficiency, normalized to the intensity of the 250.6 keV transition for Band 5 , and to $100 \%$ for the transitions depopulating each of the three isomers. The transition intensities were obtained from a combination of the total projection and gated spectra.
$T_{1 / 2}=0.48(4) \mu \mathrm{s}$ has been determined from the fit of the time spectrum with two exponential functions, the one with long half-life being necessary to account for random coincidences (see Fig. 6).

Six transitions depopulating the $21 / 2^{+}$isomeric state have been identified: four of $537,796,848$, and 1050 keV to Bands 1,3 and 4 , and two of 391 and 175 keV to the $17 / 2^{+}$and $19 / 2^{+}$isomeric states, respectively, which in turn decay to low-lying states of Bands 1 and 4 via ten transitions of 566,
$659,672,740,823,924,955,1009,1138$, and 1183 keV (see Fig. 4).

## III. DISCUSSION

## A. Spin-parity and configuration assignments to the isomers

One of the key issues is the assignment of spins and parities to the observed isomers. This was done by analyzing the

FIG. 2. Spectrum of $\gamma$ rays of Band 5 built on the $21 / 2^{+}$isomeric state measured at the target position of the JUROGAM 3 array, obtained by employing the recoil gated isomer decay tagging technique on the $848-\mathrm{keV}$ transition depopulating the isomer and on the $551-\mathrm{keV}$ transition of Band 4 detected by the germanium detectors at the MARA focal plane.
observed decay out patterns of the isomers, including the $\log F_{W}$ [38] values of the depopulating transitions, the singleparticle aligned angular momentum $i_{x}$, kinematic moment of inertia $J^{(1)}$, and total angular momentum on the rotation axis $J_{x}$ of the band built on the $2284-\mathrm{keV}$ isomeric state (see Fig. 7). In addition, the assumption widely employed in the high-spin region of well-deformed nuclei that the spin increases with increasing excitation energy is adopted.

FIG. 3. $\gamma \gamma$-coincidence spectra of the delayed transitions measured at the MARA focal plane when gating on the (a) $848-\mathrm{keV}$, (b) $537-\mathrm{keV}$, and (c) $1050-\mathrm{keV}$ transitions depopulating the $21 / 2^{+}$ isomeric state. The $267-$ and $439-\mathrm{keV}$ transitions in (b) are due to the feeding by the delayed $796-\mathrm{keV}$ transition of the $17 / 2^{+}$level of Band 3, which subsequently decays via the $535-\mathrm{keV}$ transition, contaminating thus the $537-\mathrm{keV}$ gate.

FIG. 4. (a) Singles $\gamma$-ray spectrum and (b) projection of the $\gamma \gamma$ coincidence matrix measured with the germanium detectors at the MARA focal plane, showing the ensemble of transitions depopulating the high- $K$ isomers and the states of Bands 1,3 , and 4 of ${ }^{129} \mathrm{Nd}$. The energies of the unlabeled transitions indicated with red lines are given in the text.

Figure 7 shows the experimental single-particle aligned angular momenta of the bands built on the $21 / 2^{+}$isomer in ${ }^{129} \mathrm{Nd}$ and on the $8^{-}$isomers in the $N=74$ nuclei, the kinematic moment of inertia $J^{(1)}$, and the total angular momentum on the rotation axis $J_{x}$ of the one-quasiparticle Band 1 and of the three-quasiparticle Band 5 built on the $2284-\mathrm{keV}$ isomer. Based on the lowest and highest spins of the states fed by the isomers, we concluded that their spins have to be between $17 / 2$ and $21 / 2$. The spin-parity of the $2284-\mathrm{keV}$ isomeric state can be either $17 / 2^{ \pm}, 19 / 2^{ \pm}$, or $21 / 2^{+}$. The $17 / 2^{ \pm}$and $19 / 2^{-}$assignments can be discarded because they would lead to transitions increasing spin by $1 \hbar$ for the $17 / 2^{+}$assignment $\left(17 / 2^{+} \rightarrow 19 / 2^{+}\right.$to Band 4 and $19 / 2^{+} \rightarrow 21 / 2^{-}$from the

FIG. 5. Focal plane spectra from $\gamma \gamma$ coincidences gated on the $175-$ and $391-\mathrm{keV}$ transitions from the $21 / 2^{+}$isomer, showing the depopulating transitions of the $19 / 2^{+}$and $17 / 2^{+}$isomers to states of the Bands 1,3 , and 4 . Contaminating transitions are indicated with asterisks.

FIG. 6. Time spectrum and its fit with two exponentials from which the half-life of the $21 / 2^{+}$isomeric state was determined. The spectrum is obtained with a start given by the recoils detected in the DSSD, and the stop given by the $848-\mathrm{keV}$ transition depopulating the isomer and the $551-\mathrm{keV}$ transition of Band 4 detected by the germanium detectors at the MARA focal plane.
$2109-\mathrm{keV}$ isomeric state to Band 1), or $2 \hbar$ for the $17 / 2^{-}$and $19 / 2^{-}$assignments $\left(15 / 2^{-} \rightarrow 19 / 2^{+}\right.$from the $1893-\mathrm{keV}$ isomeric state to Band 4), which are unlikely in the de-excitation of high-spin states.

The candidate configurations of the remaining $19 / 2^{+}$ and $21 / 2^{+}$possible assignments can be established from the analysis of the single-particle alignment and crossing frequency of the band built on the isomer. As one can see in Fig. 7, Band 5 above the $2284-\mathrm{keV}$ isomeric state consists of two completely degenerate signature partners and has $i_{x} \approx 1.5 \hbar$, indicating the presence of only high- $\Omega$ orbitals in its configuration. The up bend at a rotational frequency of $\hbar \omega \approx 0.35 \mathrm{MeV}$ observed in all one-quasiparticle bands of ${ }^{129} \mathrm{Nd}$ (see Fig. 6 of Ref. [29] and in Fig. 7) and in the bands built on the $8^{-}$isomers with two-neutron configurations of the $N=74$ isotones, all attributed to the alignment of a pair of $h_{11 / 2}$ protons, is absent in Band 5. With the $\left(\pi h_{11 / 2}\right)^{2}$ alignment being blocked, the configuration has to involve one $h_{11 / 2}$ proton orbital, which can be either $\pi 5 / 2^{-}$[532] or $\pi 3 / 2^{-}$[541]. For $Z=60$ and $\varepsilon_{2} \approx 0.3$, the Fermi surface is in the middle of the $h_{11 / 2}$ subshell where the $\pi 5 / 2^{-}$[532] Nilsson orbital is closest in energy, being therefore favored. To establish the orbital occupied by the second proton in the isomer configuration, we observe that $J^{(1)}$ of Band 5 is smaller than that of Band 1 above the up bending, where two rotationally aligned $h_{11 / 2}$ protons are present, suggesting that the second proton occupies a high- $\Omega$ orbital, like $\pi 9 / 2^{+}$[404] or $\pi 5 / 2^{+}$[413], which by having the angular momenta perpendicular to the rotation axis have tiny contributions to $J^{(1)}$. The neutron has to be placed in a negative-parity orbital to get the positive parity of the isomer, which can only be $v 7 / 2^{-}[523]$. We

FIG. 7. (a) Single-particle aligned angular momenta for the bands built on the $21 / 2^{+}$isomer in ${ }^{129} \mathrm{Nd}$ and for the $8^{-}$isomers in the $N=74$ nuclei. The Harris parameters are $J^{(0)}=$ $14 \hbar^{2} \mathrm{MeV}^{-1}$ and $J^{(2)}=38 \hbar^{4} \mathrm{MeV}^{-3}$ for the $N=74$ isomers, and $J^{(0)}=38 \hbar^{2} \mathrm{MeV}^{-1}$ and $J^{(2)}=15 \hbar^{4} \mathrm{MeV}^{-3}$ for the $21 / 2^{+}$isomer in ${ }^{129} \mathrm{Nd}$; (b) experimental kinematic moments of inertia $J^{(1)}$; (c) projections on the cranking axis of the total angular momentum $J_{x}$ for Bands 1 and 5 of ${ }^{129} \mathrm{Nd}$.
therefore acknowledge two candidates for the threequasiparticle configuration of the $2284-\mathrm{keV}$ isomeric state, $\quad\left\{\nu 7 / 2^{-}[523] \otimes \pi\left(9 / 2^{+}[404] 5 / 2^{-}[532]\right)\right\}_{21 / 2^{+}} \quad$ and $\left\{\nu 7 / 2^{-}[532] \otimes \pi\left(9 / 2^{+}[404] 3 / 2^{-}[541]\right)\right\}_{19 / 2^{+}}$.

From the analysis of the $\log F_{W}$ values of the depopulating transitions one conclude that both $19 / 2^{+}$or $21 / 2^{+}$ assignments nicely fits the systematics of the $E 2, M 1$, and $E 1$ transitions depopulating high- $K$ isomers [38] for all

FIG. 8. Calculations for the $\nu 7 / 2^{-}[523] \otimes \pi\left(9 / 2^{+}[404] 5 / 2^{-}[532]\right)$ configuration assigned to the $21 / 2^{+}$isomeric state: (a) Potential energy surface calculated with the CC-PES model; (b) Comparison between the experimental kinematic moment of inertia $J^{(1)}$ of Band 5 and the PNC-CSM calculations. (c) Comparison between the experimental Band 5 and the PSM calculations, using deformation parameters $\varepsilon_{2}=0.35$ and $\varepsilon_{4}=0.02$ which best reproduce the band-head and level energies.
transitions excepting the $175-$ and $391-\mathrm{keV}$ ones. The 391keV transition has higher hindrance for both $E 2$ and $M 1$ characters, whereas the $175-\mathrm{keV}$ transition has higher hindrance only for $M 1$ character. The high hindrances of these two transitions would be in agreement with the systematics of the high- $K$ isomers only if $\Delta K \geqslant 3$, which would lead to too low spins for the isomers that in turn would decay to levels with spins higher by more than $2 \hbar$ than that of the initial states, and therefore can be discarded. To explain the $\log F_{W}$ values of the $175-$ and $391-\mathrm{keV}$ transitions we have to invoke the presence of additional hindrances, which can be induced by very different configurations or different deformations of the isomers.

In order to further investigate the configuration of the $21 / 2^{+}$isomeric state, the mixing ratios of the $\Delta I=1$ and $\Delta I=2$ transitions depopulating a given state of spin $I$ of the band built on the isomer have been estimated from the transition intensities employing standard formulas valid in the approximation of an axially symmetric rotating nucleus [39,40]:

$$
\begin{gather*}
\frac{\delta^{2}}{1+\delta^{2}}=\frac{2 K^{2}(2 I-1)}{(I+1)(I-1+K)(I-1-K)} \frac{E_{1}^{5}}{E_{2}^{5}} \frac{T_{2}}{T_{1}}  \tag{1}\\
\frac{g_{K}-g_{R}}{Q_{0}}=\frac{0.933 E_{1}}{\delta \sqrt{\left(I^{2}-1\right)}} \tag{2}
\end{gather*}
$$

where $\delta$ is the mixing ratio, $E$ is the transition energy in MeV , $T$ is the $\gamma$-ray transition intensity, and $Q_{0}$ is in units of $e \mathrm{~b}$. The subscripts 1,2 refer to $\Delta I=1,2$ transitions, respectively. The $|\delta|$ values can be estimated from Eq. (1) by assuming a certain $K$ value, whereas the sign of $\delta$ can be obtained from the analysis of the angular correlations of the emitted $\gamma$ rays. From Eq. (1) one obtains $|\delta| \approx 0.5$. If the $\delta$ values are positive, the $\left(g_{K}-g_{R}\right) / Q_{0}$ values are also positive for a prolate shape [41]. To estimate $g_{K}$ we can adopt a smaller gyromagnetic factor of $g_{R}=0.3$ than the rotational approximation $g_{R}=Z / A=0.46$, as suggested by that recently observed experimentally for the $8^{-}$high- $K$ isomer in ${ }^{130} \mathrm{Ba}$, for which $g_{R}=0.278(15)$ has been extracted instead of $g_{R}=Z / A=$ 0.43 [42]. We can also adopt an intrinsic quadrupole mo-
ment of $Q_{0}=5.5 \mathrm{eb}$ corresponding to an axially symmetric prolate shape with a deformation of $\beta_{2}=0.3$, as suggested by the calculations. With this adopted values, one obtains a gyromagnetic factor of $g_{K} \approx 0.3+\frac{0.11}{\delta} \approx 0.53$ for $I=12.5$. Very similar values are obtained for higher spins. This has to be compared with calculated $g_{K}$ values for different threequasiparticle configurations, which are $\approx 0$ for three-neutron configurations, and $\approx+1$ for one neutron-two proton configurations. One can therefore conclude that the configuration involving two protons is favored. This conclusion is also supported by the mixing ratios that could be extracted for the 251- and $298-\mathrm{keV}$ transitions of Band 5, which are positive and around $0.36_{-9}^{+23}$ (see Table I), in fair agreement with the estimated absolute values extracted using the relations (1) and (2). For an oblate shape such a conclusion is not valid, but, as will be discussed in the following subsection, the oblate configuration can be safely discarded, because the calculated energy is too high and no minimum for an oblate shape is calculated in the potential energy surfaces.

The spin-parity of the $1893-\mathrm{keV}$ state is fixed as $17 / 2^{+}$ by the $391-\mathrm{keV}$ populating transition from the $21 / 2^{+}$isomer and the $1009-\mathrm{keV}$ depopulating transition to the $13 / 2^{+}$ state of Band 4 which have to be $E 2$ otherwise one transition would be $\Delta I=1$ and the other one $\Delta I=3$ which is very unlikely. The spin-parity of the $2109-\mathrm{keV}$ state is fixed as $19 / 2^{+}$by the $955-\mathrm{keV}$ transition to the $15 / 2^{+}$state of Band 4, the $566-\mathrm{keV}$ transition to the $21 / 2^{-}$state of Band 1, and the $175-\mathrm{keV}$ transition from the $21 / 2^{+}$isomeric state. These assignments are also in agreement with the results of the calculations described in the following subsection. Very different configurations have to be chosen for the $19 / 2^{+}$and $17 / 2^{+}$isomeric states, since no transition has been observed between them. This can be realized if we adopt the $v 7 / 2^{-}[523] \otimes \pi\left(5 / 2^{+}[413] 5 / 2^{-}[532]\right)$ configuration for the $17 / 2^{+}$isomeric state, which differs by two proton and one neutron excitations from the $v 5 / 2^{+}[402] \otimes$ $\pi\left(9 / 2^{+}[404] 5 / 2^{+}[413]\right)$ configuration assigned to the $19 / 2^{+}$ isomeric state. Moreover, this configuration is similar to the $\nu 7 / 2^{-}[523] \otimes \pi\left(9 / 2^{+}[404] 5 / 2^{-}\right.$[532] $)$configuration of the $21 / 2^{+}$isomeric state, from which it differs by one proton

TABLE II. Calculated energies of the assigned configurations to the three high- $K$ isomers. The configurations are given in terms of Nilsson quantum numbers. The shape parameters $\left(\beta_{2}, \gamma\right)$ resulting form the CC-PES calculations, as well as the adopted quadrupole deformations $\varepsilon_{2}$ for the PNC-CSM and PSM calculations are also indicated. The approximate relation between $\beta_{2}$ and $\varepsilon_{2}$ is $\varepsilon_{2} \approx 0.95 \beta_{2}$.

| $I^{\pi}$ | $E_{x}^{\exp }(k e V)$ | Configuration | CC $-\operatorname{PES}\left(\beta_{2}, \gamma\right)$ | PNC-CSM $\left(\varepsilon_{2}\right)$ | $P S M\left(\varepsilon_{2}\right)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $21 / 2^{+}$ | 2284 | $\nu 7 / 2^{-}[523] \pi 9 / 2^{+}[404] 5 / 2^{-}[532]$ | $2605\left(0.31,-4^{\circ}\right)$ | $3272(0.31)$ | $2247(0.35)$ |
| $19 / 2^{+}$ | 2109 | $\nu 7 / 2^{-}[523] \pi 9 / 2^{+}[404] 3 / 2^{-}[541]$ | $3016\left(0.29,-6^{\circ}\right)$ | $4973(0.29)$ | $3195(0.35)$ |
| $19 / 2^{+}$ | 2109 | $\nu 5 / 2^{+}[402] \pi 9 / 2^{+}[404] 5 / 2^{+}[413]$ | $3210\left(0.29,-8^{\circ}\right)$ | $3992(0.29)$ | $2786(0.35)$ |
| $17 / 2^{+}$ | 1893 | $\nu 7 / 2^{-}[523] \pi 5 / 2^{+}[413] 5 / 2^{-}[532]$ | $3044\left(0.28,0^{\circ}\right)$ | $2421(0.28)$ | $2836(0.35)$ |
| $17 / 2^{+}$ | 1893 | $\nu 5 / 2^{+}[402] \pi 9 / 2^{+}[404] 3 / 2^{+}[411]$ | $2702\left(0.30,9^{\circ}\right)$ | $4658(0.30)$ | $3092(0.35)$ |

excitation, being thus in agreement with the observation of the connecting $391-\mathrm{keV}$ transition.

The $17 / 2^{+}$and $19 / 2^{+}$states at 1893 and 2109 keV , respectively, have decay patterns similar to those of the 2284$\mathrm{keV} 21 / 2^{+}$isomeric state, suggesting high- $K$ configurations and isomeric character. Their half-lives could not be directly determined in the present experiment. For estimating their half-lives, we analyzed the Weisskopf hindrance factors $\log F_{W}=\log \frac{\tau_{\gamma}}{\tau_{W}}$ of the depopulating transitions ( $\tau_{\gamma}$ is the partial $\gamma$-ray lifetime and $\tau_{W}$ is the Weisskopf estimate), which depend on the electromagnetic character of the transition and increase nearly linearly with $\Delta K$ [38]. It was found that they are compatible with high $\Delta K$ values ranging between 3 and 4 for half-lives of tens of nanoseconds, between 5 and 6 for half-lives of a few hundreds nanoseconds, and between 6 and 7 for half-lives of a few microseconds, giving support to their high- $K$ nature. By imposing that the $\log F_{W}$ values of the depopulating transitions are in agreement with the systematics [38], the best agreement was obtained for half-lives between several nanoseconds and tens of nanoseconds for both isomers. The decreasing half-lives of the three high- $K$ isomers $21 / 2^{+}, 19 / 2^{+}$, and $17 / 2^{+}$can be partially related to their increasing energy relative to the yrast line.

The transitions from the isomer to the previously known bands fix the absolute energies of Bands 1,3 , and 4 , and at the same time confirm the relative energies of Bands 3 and 4 established in Ref. [29]. A new 406-keV E2 transition from the $9 / 2^{+}$state of Band 3 to the $5 / 2^{+}$band-head of Band 4 has been identified, which confirms the assigned relative spins and positive parity of Bands 3 and 4 [29]. The present results provide evidence that the ground state of ${ }^{129} \mathrm{Nd}$ is $7 / 2^{-}$, the band-head of Band 1 , not $5 / 2^{+}$, the band-head of Band 4 , as presently adopted by ENSDF [43]. We found that the $5 / 2^{+}$ band-head of Band 4 decays via two delayed transitions of 69 and 108 keV to the $3 / 2^{+}$state of Band 3 and the newly assigned $7 / 2^{-}$ground state, respectively. These transitions have been observed at the focal plane of MARA in coincidence with the $848-\mathrm{keV}$ transition depopulating the $21 / 2^{+}$isomeric state, and also in delayed coincidence with the transitions of Band 4 below the $19 / 2^{+}$state, the highest fed by depopulating transitions from the $21 / 2^{+}$isomeric state. However, they were not observed in prompt coincidence with transitions of Band 4 above the $19 / 2^{+}$level. This indicates that the $5 / 2^{+}$ band-head of Band 4 is isomeric, with a half-life of a few tens of nanoseconds. An indirect confirmation of the isomeric
character of the $108-\mathrm{keV}, 5 / 2^{+}$state is the nonobservation of the $69-\mathrm{keV}$ transition in the previous experiment of Zeidan et al. [29], in which only prompt coincidences were measured. In the present experiment we also used a thin target, but unlike the Zeidan et al. experiment [29], we were able to observe the delayed 69- and $108-\mathrm{keV}$ transitions emitted at the focal plane of the MARA separator due to the feeding of Band 4 by transitions from the long-lived $21 / 2^{+}$isomeric state.

The lowest states of Band 3 with spins $1 / 2^{+}$and $3 / 2^{+}$ have excitation energies of 17 and 39 keV , respectively. Their decays to the $7 / 2^{-}$ground state via low-energy E3 and $M 2$ transitions would be extremely hindered, they most

FIG. 9. Results of PSM calculations [11] for Bands 1, 2, 3, and 4 of ${ }^{129} \mathrm{Nd}$, adopting $\varepsilon_{2}=0.29$ and $\varepsilon_{4}=0.02$ taken from Ref. [45], in comparison with the data of this work and those from Ref. [29].

FIG. 10. Calculated $E(J)$ and $E_{\gamma}=E(J)-E(J-1)$ values for Band 5 in ${ }^{129} \mathrm{Nd}$ with the projected shell model [11], assuming prolate and oblate shapes, with deformation parameters $\varepsilon_{2}= \pm 0.30$ and $\varepsilon_{2}=0.04$.
probably $\beta$ decay with a half-life of $T_{1 / 2}=2.6 \mathrm{~s}$, as proposed in Ref. [30].

Band 2 remains floating, as no connecting transitions from the $21 / 2^{+}$isomeric state or to low-lying states have been identified. As Band 2 is the weakest among the four onequasiparticle bands of ${ }^{129} \mathrm{Nd}$ [29], it is unlikely that its band head is close or lower than the $1 / 2^{+}, 3 / 2^{+}$states of Band 3 towards it can decay. For this reason Band 2 is drawn in Fig. 1 more excited than the other bands.

Finally, it is worth noting that from the present experiment we did not find evidence of the $\left(7 / 2^{-}\right)$isomer with half-life of $\approx 7 \mathrm{~s}$ proposed in the ENSDF compilation [43].

## B. Theoretical calculations

In order to check if and to what extent the spin-parity and configuration assignments to the newly identified isomers is supported by various nuclear models, we performed several calculations. The deformations and excitation energies of the high- $K$ isomers are summarized in Table II. The calculations with the three models CC-PES, PSM, and PNC-CSM for the $\nu 7 / 2^{-}[523] \otimes\left(\pi 9 / 2^{+}[404] 5 / 2^{-}[532]\right)$ configuration assigned to the $21 / 2^{+}$isomeric state are shown in Fig. 8.

As will be discussed in the following, all three employed models calculate the $21 / 2^{+}$state lower in energy than the possible $19 / 2^{+}$and $17 / 2^{+}$states. Therefore, the natural
spin-parity assignment for the $2284-\mathrm{keV}$ isomeric state is $21 / 2^{+}$. However, one cannot simply discard the $19 / 2^{+}$assignment without justification. There are two possible 19/2+ configurations, $v 7 / 2^{-}[523] \otimes \pi\left(9 / 2^{+}[404] 3 / 2^{-}[541]\right)$ and $v 5 / 2^{+}[402] \otimes \pi\left(9 / 2^{+}[404] 5 / 2^{+}[413]\right)$, which are calculated by CC-PES using the Woods-Saxon potential in an inverse order than that calculated by PSM and PNC-CSM using the Nilsson potential (see Table II). We therefore have to analyze two possible scenarios for the $19 / 2^{+}$assignment to the 2284keV isomeric state, one based on the order resulting from the CC-PES and PNC-CSM calculations, and one based on the order resulting from the PSM calculations. However, the E2 component of the $175-\mathrm{keV}$ transition between the two $19 / 2^{+}$ configurations appears to be not additionally hindered in both scenarios, even though it would connect states with very different configurations. The $19 / 2^{+}$assignment can therefore be discarded. The higher hindrance of the $175-\mathrm{keV}$ transition, if of $M 1$ character, can be explained if one selects the $\nu 5 / 2^{+}[402] \otimes \pi\left(9 / 2^{+}[404] 5 / 2^{+}[413]\right)$ configuration for the $19 / 2^{+}$isomeric state, which differs by both neutron and proton single-particle excitations from that of the $21 / 2^{+}$isomeric state, leading to a low overlap between the wave functions (see the following discussion), while the higher hindrance of the $391-\mathrm{keV}$ transition connecting states with configurations involving proton orbitals with different deformation driving forces $\left(\pi 9 / 2^{+}[404]\right.$ towards higher deformation and $\pi 5 / 2^{+}[413]$ flat for prolate deformation) can be explained by the calculated different deformations of the $21 / 2^{+}\left(\beta_{2}=\right.$ $0.31)$ and $17 / 2^{+}\left(\beta_{2}=0.28\right)$ states (see Table II). The $21 / 2^{+}$ assignment corresponds in fact to the maximum spin that can be obtained with available orbitals around the proton and neutron Fermi surfaces for a prolate deformation of $\varepsilon_{2}=$ 0.3 . In conclusion, we adopt the $21 / 2^{+}$spin-parity and the $\nu 7 / 2^{-}[523] \otimes \pi\left(9 / 2^{+}[404] 5 / 2^{-}[532]\right)$ configuration for the $21 / 2^{+}$isomeric state.

## 1. CC-PES calculations

First we performed CC-PES calculations to investigate if the isomers are based on oblate shapes. No minimum was found for oblate deformations for any configuration involving proton and neutron orbitals close to the Fermi surface. We therefore discarded the oblate shapes for the observed isomers. All possible one-quasiparticle and three-quasiparticle configurations involving orbitals close to the Fermi surfaces for prolate deformations have been calculated, employing a Woods-Saxon potential and Lipkin-Nogami pairing [10]. For each quasiparticle configuration, the occupied orbitals were fixed and the deformation parameters $\left(\beta_{2}, \gamma, \beta_{4}\right)$ were varied in order to minimize the excitation energies. The neutron and proton monopole pairing strengths were determined by the average gap method [44]. The results of various one- and three-quasiparticle configurations are summarized in Table III. They all have nearly axially symmetric prolate shapes with deformations between $\beta_{2} \approx 0.28$ and $\beta_{2} \approx 0.32$, and moderate triaxialities between $-8^{\circ}$ and $15^{\circ}$. The lowest excited one-quasiparticle configurations, normalized to the lowest calculated one, are those assigned to Bands 1,3 , and $4: 0,53$, and 153 keV for Bands 1, 4, and 3, respectively, being in

good agreement with the experimental energies which are in a narrow interval of $\approx 100 \mathrm{keV}$. Band 2 is calculated to be much more highly excited, at 1200 keV , which can thus explain its lower intensity [29] and the lack of observed connecting transitions with the other bands. The $v 7 / 2^{-}[523] \otimes$ $\pi\left(9 / 2^{+}[404] 5 / 2^{-}[532]\right)$ configuration that we assign to the $21 / 2^{+}$isomeric state is calculated at 2.605 MeV , and has a nearly axially symmetric prolate shape with $\beta_{2}=0.31$ and $\gamma=-4^{\circ}$ (see Fig. 8(a). The three-quasiparticle candidate configurations for the $17 / 2^{+}$and $19 / 2^{+}$isomeric states are calculated at higher energies and slightly smaller deformations than those of the $21 / 2^{+}$isomeric state.

## 2. PSM calculations

The structure of the one-quasiparticle bands has also been investigated using the PSM, using slightly different quadrupole deformations than those suggested by the CC-PES calculations. Results of the calculations for Bands $1,2,3$, and 4, adopting $\varepsilon_{2}=0.29$ and $\varepsilon_{4}=0.02$ taken from Ref. [45], are shown in Fig. 9. Both the energies and the observed signature staggering below the up bending are nicely reproduced in all bands, which are essential prerequisites for obtaining
good agreement for the three-quasiparticle configurations. The bands have been calculated up to very high excitation energy, to investigate their evolution with increasing spin. The ground state with $I^{\pi}=7 / 2^{-}$is reproduced, which is different from Ref. [29]. The band-head energies for Bands 3 and 4 are well described with PSM, as $19 \mathrm{keV}(17 \mathrm{keV})$ and $192 \mathrm{keV}(108 \mathrm{keV})$, respectively. For the floating Band 2, the PSM gives 785 keV as the band-head energy. The states with spin lower than about $23 / 2$ are reproduced nicely, including the energies and signature staggering, while some discrepancies show up for Bands 2 and 4 at high spin. Band 1 is well described up to the highest spin 75/2, where 5-quasiparticle configurations are found to be important.

One important conclusion resulting from the PSM calculations is that the possible oblate configuration $v 5 / 2^{+}[402] \otimes$ $\left(\pi 5 / 2^{+}[402] 9 / 2^{-}[514]\right)$ is calculated higher relative to the prolate $\nu 7 / 2^{-}[402] \otimes\left(\pi 9 / 2^{+}[404] 5 / 2^{-}[532]\right)$ configuration, and with definitely larger curvature of the $E$ versus $J$ and corresponding smaller moment of inertia $J^{(1)}$ (see Fig. 10), which corroborates the results of the CC-PES calculations, inducing us to confidently assign the configuration built on the prolate shape for the $21 / 2^{+}$isomeric state. One can note the following weak points of the PSM results, due to

the assumed axial deformation, which however have no impact on the isomer interpretation: a lower signature staggering both before the up bending and at the highest observed spins in Band 1, opposite staggering at the bottom and after the up bending in Band 2, a slightly lower staggering in Band 3, and opposite staggering in Band 4 above the up bending.

## 3. PNC-CSM calculations

The PNC-CSM calculations give reasonably good results for Bands 1, 3, and 4, but failed to reproduce the observed gradual up bending in the positive signature partner for Band 2 (see Fig. 11). Three quasiparticle configurations have also been calculated. Two of them are shown in Fig. 8(b), where one can see that $J^{(1)}$ of the $v 7 / 2^{-}[523] \otimes$ $\left(\pi 9 / 2^{+}[404] 5 / 2^{-}[532]\right)$ configuration assigned to the $21 / 2^{+}$ isomeric state is calculated closest to the experimental one over a large frequency interval. However, the calculated split-
ting between the signature partners at high frequency is not observed in the experiment. A larger deformation can reproduce better the $J^{(1)}$ values, but the inherent lowering of the $\nu 1 / 2^{-}$[541] intruder and its interaction with the negativeparity $h_{11 / 2}$ orbitals induces an unobserved perturbation at high frequency.

Table IV shows the results of the PNC-CSM calculations of one- and three-quasiparticle configurations in ${ }^{129} \mathrm{Nd}$. The deformation parameters are taken from Möller and Nix's Table of 1995 [46]. To reproduce better the experimental band-head energies, some of them are adopted from the CC-PES calculated deformations in Table II. In particular, the deformation $\varepsilon_{2}=0.310$ is adopted for the newly observed band built on the $2284-\mathrm{keV}$ isomer, which leads to a good agreement with both of the experimental state energy and the kinematic moment of inertia shown in Fig. 8(b). This suggests that for excited multi-quasiparticle configurations the CC-PES calculated deformations can be better than the Möller and Nix ones.

FIG. 11. Comparison of the kinematic moment of inertia $J^{(1)}$ calculated with PNC-CSM and the experimental data for Bands 1 , 2, 3, and 4 in ${ }^{129} \mathrm{Nd}$.

## IV. SUMMARY

In summary, the present study of ${ }^{129} \mathrm{Nd}$, the lightest isotope known spectroscopically in the odd-even neodymium sequence, lead to the identification of three high- $K$ isomers and one low-spin isomer, as well as the reassignment of the ground state spin-parity to $7 / 2^{-}$. This is the first observation
of a three-quasiparticle isomer in the $A \approx 130$ mass region close to the proton drip line. From the analysis of the transitions depopulating the $21 / 2^{+}$isomeric state we extracted its half-life, while from the analysis of the Weisskopf hindrance factors of the depopulating transitions we tentatively assigned the spin-parity. From the analysis of the band built on the isomer combined with the results of CC-PES, PSM, and PNC-CSM calculations we assigned three-quasiparticle prolate configurations involving one neutron and two protons to all three high- $K$ isomers. The present results represent the first example of high- $K$ isomers involving the $\pi 9 / 2^{+}$[404] orbital in nuclei with $Z$ well above the $Z=50$ shell closure, suggesting the existence of such isomers in other nuclei close to the proton drip line in the $A \approx 130$ mass region, which hopefully will be discovered in the future.
