Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.
The H₂C(X)–X···X⁻ (X = Cl, Br) Halogen Bonding of Dihalomethanes

Abstract

The dihalomethane–halide H₂C(X)–X···X⁻ (X = Cl, Br) halogen bonding was detected in a series of the cis-[PdX(CNCy){NHCy}=NHC₆H₂Me₂NH₂]X•CH₂X₂ (X = Cl, Br) associates by single-crystal XRD followed by DFT calculations. Although ESP calculations demonstrated that the σ-hole of dichloromethane is the smallest among all halomethane solvents (the maximum electrostatic potential is only 2.6 kcal/mol), the theoretical DFT calculations followed
by Bader’s QTAIM analysis (M06/DZP-DKH level of theory) confirmed the H₂C(X)–X•••X–
halogen bond both in the solid state and gas phase optimized geometries. The estimated bonding
ingerlies in H₂C(X)–X•••X– is in the 1.9–2.8 kcal/mol range.

Introduction

Orientation of solvent molecules around anions is intensively studied in crystal engineering,
solution and colloid chemistry, and also in catalysis.1–7 Among different anions, halides play
especially important chemical and biological roles, in particular, in asymmetric catalysis,8–10
design of artificial anion receptors, and in the ionic homeostasis of the living cells.11–15 In most
cases, solvation of halide anions proceeds through hydrogen bonding (HB) with solvent
molecules.

Halomethanes—apart from positive H centers responsible for HBs—featuring an
alternative type of partial positive charge centers, viz. the σ-holes16 of covalently bound chlorine,
bromine, or iodine atoms, which may be responsible for non-covalent contacts. The calculations
conducted by us in this work (Table 1, Figure 1) and previously by some other groups17–19 (for
more details see Supporting information, Table SI1) clearly indicate that the values of
electrostatic potential on the σ-holes, and correspondingly the ability of forming XBs,
substantially depend on amount and type of halogen atoms in the halomethanes. These XBs were
widely studied for effective halomethane XB donors (CBr₄,19–21 CHI₃,22,23 CFBBr₃,19 CCl₃Br,24 and
CHBr₃;19,20 for full description of the C–X•••X– XBs, the X•••X– distances and the ∠(C–X•••X–)
angles see Supporting information, Table SI2), whereas the relatively inactive (Table 1, Figure
1) XB donors such as CCl₄ and CHCl₃ quite rarely form XBs.25–26
Table 1. Maximum electrostatic potentials \( (V_s(r)_{max}, \text{kcal/mol}) \) on the halogen atoms calculated (see Experimental) on the 0.001 a.u. molecular surfaces for CH\(_3\)X, CH\(_2\)X\(_2\), CHX\(_3\), and CX\(_4\) (X = Cl, Br, I) structures optimized (the M06-2X/CEP-121G level of theory) in gaseous phase (“values” of σ-holes). The “values” of σ-holes as a percentage of the maximal are given in parentheses.

Figure 1. ESP distribution in the CH₅X₄−ₙ (X = Cl, Br, I; n = 1–3) halomethane molecules.

Until now only a few publications were devoted to XBs in condensed phases involving CH₂Cl₂, as the weakest σ-hole donor among halomethane solvents, and also with its bromine congener, CH₂Br₂. Thus, the possibility of CH₂Cl₂ to behave as XB donor was acknowledged by statistical analyses of CCDC structures conducted by Allen et al.²⁷ and Mooibroek et al.²⁸ In the former report,²⁷ a possibility for the formation of various H₂C(Cl)–Cl•••X–C (X = Cl, Br, I) short contacts was indicated, but the angle parameters were not specified and therefore the ability of CH₂Cl₂ behave as XB donor was not fully confirmed. The latter article²⁸ gives certain statistical evidences favoring H₂C(Cl)–Cl•••D (D = F, Cl, Br, I, N, O, S) contacts, which can be treated as dichloromethane-involved XBs.
Rodríguez and Bertrán\textsuperscript{29} conducted NMR correlation analysis for CH\textsubscript{2}X\textsubscript{2} (X = Cl, Br, I) in solvents of different basicity. The observed differences in \textsuperscript{1}H chemical shifts indicated that behavior of CH\textsubscript{2}Cl\textsubscript{2} and CH\textsubscript{2}Br\textsubscript{2} in these solutions is almost the same and the contribution of XBs to the solvation process is expected to be identical. Insofar as it was assumed\textsuperscript{29} that CH\textsubscript{2}Cl\textsubscript{2} forms only HB, it collaterally means that CH\textsubscript{2}Br\textsubscript{2} does not form XBs in solutions. Jin \textit{et al.}\textsuperscript{17} recently carried out EPR correlation study of the solvation of 2,2,6,6-tetramethyl-1-piperidin-1-yl oxy free radical (TEMPO) by various solvents—including CH\textsubscript{2}Cl\textsubscript{2} and CH\textsubscript{2}Br\textsubscript{2}—and found that the solvation is different in halogenated and in halogen-free solvents because of the C–X•••O–N XB. Subsequent theoretical calculations demonstrated comparable energies of HB and XB in the observed solvent–TEMPO weak interactions.

In the solid state, dibromomethane forms the H\textsubscript{2}C(Br)–Br•••Br–C,\textsuperscript{30,31} H\textsubscript{2}C(Br)–Br•••O,\textsuperscript{32} and H\textsubscript{2}C(Br)–Br•••N\textsuperscript{33} types of XB. Concurrently, XBs involving CH\textsubscript{2}Cl\textsubscript{2} as the weakest XB donor among halomethane solvents, were described only in three works. The H\textsubscript{2}C(Cl)–Cl•••Cl–C XBs were found in the crystalline CH\textsubscript{2}Cl\textsubscript{2}\textsuperscript{34} and the unusual H\textsubscript{2}C(Cl)–Cl•••N≡[Os] halogen bonds were discussed in a review.\textsuperscript{35} Eventually, some of us recently reported that CH\textsubscript{2}X\textsubscript{2} (X = Cl, Br) form the H\textsubscript{2}C(X)–X•••Cl–[Pt] (X = Cl, Br) XBs with chloride ligands in platinum(II) PANT complexes.\textsuperscript{36} In the context of this work, one should stress that XBs of CH\textsubscript{2}Cl\textsubscript{2} or CH\textsubscript{2}Br\textsubscript{2} with \textit{any of the halide anions} are yet unreported.

Previously we demonstrated that cationic 1,3,5-triazapentadienato nickel(II) and platinum(II) complexes can be used as scaffolds for a numerous solvent–chloride clusters held by simultaneous HBs\textsuperscript{26,37-40} and XBs.\textsuperscript{26} We now expand a range of metal-based platforms, which can be applied for recognition of novel types of XB, by using acyclic dianimocarbene
palladium(II) complexes (Scheme 1) known as catalysts for various organic transformations.\textsuperscript{41-47} We found that these palladium species can be co-crystallized with very weak XB donors such as dichloromethane and dibromomethane giving solvates featuring $\text{H}_2\text{C}(\text{X})\cdots\text{X}^-$ (X = Cl, Br) XBs and our findings are the first recognition of XB between uncomplexed halides and dihalomethanes.

**Results and Discussion**

Recently we reported\textsuperscript{48,49} the reaction between $\text{cis-}[\text{PdCl}_2(\text{CN}^\text{R}^1)_2]$ (1) and benzene-1,2-diamines (2) that leads to the $\text{cis-}[\text{PdCl}(\text{CN}^\text{R}^1)\{\text{Cl}(\text{N}^\text{R}^1)=\text{NHC}_6\text{H}_5(\text{R}^2)_2\text{NH}_2\}]\text{Cl}$ (R\textsuperscript{1} = Cy (cyclohexyl), 2-Cl-6-MeC\textsubscript{6}H\textsubscript{3}, 2,6-Me\textsubscript{2}C\textsubscript{6}H\textsubscript{3}; R\textsuperscript{2} = H, Me, Cl, 3a–d) complexes bearing Cl$^-$ as the counterion (Scheme 1). Complexes 3b, 3c, and 3d (Table 1) were characterized by single-crystal X-ray diffraction (XRD) as dichloromethane solvates 3b$\cdot$CH\textsubscript{2}Cl\textsubscript{2}, 3c$\cdot$1½CH\textsubscript{2}Cl\textsubscript{2}, and 3d$\cdot$CH\textsubscript{2}Cl\textsubscript{2}$\cdot$H\textsubscript{2}O (Figure 2, left).\textsuperscript{48,50} In these three structures, only N–H$\cdots$Cl$^-$, O–H$\cdots$Cl$^-$ (in 3d$\cdot$CH\textsubscript{2}Cl\textsubscript{2}$\cdot$H\textsubscript{2}O), and C–H$\cdots$Cl$^-$ hydrogen bonds were observed and no halogen bonds were detected.

Figure 2. The environment of Cl\(^{–}\) in previously reported solvates 3b\(\cdot\)CH\(_2\)Cl\(_2\), 3c\(\cdot\)1\(\frac{1}{2}\)CH\(_2\)Cl\(_2\), and 3d\(\cdot\)CH\(_2\)Cl\(_2\)•H\(_2\)O (left) and in 3a\(\cdot\)CH\(_2\)Cl\(_2\) studied in this work (right).

We now found that 3a is crystallized with dichloromethane giving 3a\(\cdot\)CH\(_2\)Cl\(_2\), where the 
H\(_2\)C(Cl)–Cl⋯Cl\(^{–}\) short contacts (Figure 2, right) were identified. These contacts can be 
interpreted as XB)s accordingly to the IUPAC “distance” and “angle” criteria.\(^{51}\) Indeed, the 
distances d(Cl⋯Cl) = 3.276(3) and 3.236(3) Å are sufficiently less than the sum of the 
Rowland’s vdW\(^{52}\) radii (2R\(_{vdw}(Cl) = 3.52\) Å) and the angles \(\angle(C–Cl⋯Cl) = 166.3(3)\) and 
166.2(4)° are close to 180°. We found that only 3a, among all other species derived from the 
coupling with benzene-1,2-diamine, gives dichloromethane solvate with XB. We believe that this 
is due to the crucial role of the shape of the molecular cation of 3a in the crystal packing and, 
consequently, in the formation of XB. The replacement of cyclohexyl substituents to aryls in the 
starting complex and methyl substituents to chlorine atoms in the starting nucleophile lead to 
another environment of the chloride anion (Figure 2, left) and even to another 
complex:dichloromethane ratio in 3c\(\cdot\)1\(\frac{1}{2}\)CH\(_2\)Cl\(_2\) and to the inclusion of water in 
3d\(\cdot\)CH\(_2\)Cl\(_2\)•H\(_2\)O.
We also succeeded to perform the CH$_2$Cl$_2$/CH$_2$Br$_2$ isostructural exchange with complete preservation of the solvent environment in 3a•CH$_2$Br$_2$. In the X-ray structure of 3a•CH$_2$Br$_2$, the H$_2$C(Br)–Br•••Cl–XBs were found (d(Br•••Cl) = 3.1911(11) Å is less than Rowland’s R$_{vdW}$(Cl) + R$_{vdW}$(Br) = 3.63 Å, and $\angle$(C–Br•••Cl) is 167.3(2)°). Despite significant difference in the cell parameters of 3a•CH$_2$Cl$_2$ and 3a•CH$_2$Br$_2$, these two species demonstrate similar crystal structures, and positions of each complex cation, chloride anion, and solvent molecule are almost the same (Figure 3, a–b).

To expand a number of dihalomethane–halide clusters, complex 4 was obtained by the metathetical reaction of 3a with KBr (Scheme 1), whereupon 4 was co-crystallized with CH$_2$Cl$_2$ and CH$_2$Br$_2$ forming solvates 4•CH$_2$Cl$_2$ and 4•CH$_2$Br$_2$, respectively. In the structure of 4•CH$_2$Cl$_2$, the positions of the complex cations and bromide counterions are close to those found for 3a•CH$_2$Cl$_2$, but solvent molecules are arranged differently and the Cl$_2$C(H)–H•••Br HBS were found instead XB (Figure 3, c). This observation can be accounted for by the lower XB energy in the case of CH$_2$Cl$_2$ than that in CH$_2$Br$_2$ (see theoretical considerations for details later). The difference between 3a•CH$_2$Cl$_2$ and 4•CH$_2$Cl$_2$ in terms of their ability of forming XB vs. HBS, were also indirectly observed by IR spectroscopy in the solid state (see SI, Figure SIV4), when we found a change of shapes of the antisymmetric C–Cl stretches. The high temperature (300 K) XRD experiment for 4•CH$_2$Cl$_2$ indicated that CH$_2$Cl$_2$ is fully disordered, occupying at least three different positions and therefore reliable information on solvent-involved weak interactions could not be obtained.

In the case of 4•CH$_2$Br$_2$, the released single-crystals are unstable at 100 K probably due to a phase transition and data collection was performed at 200 K. The structure of 4•CH$_2$Br$_2$ is close to 3a•CH$_2$Br$_2$ (Figure 3, d and Figure 4, d), and the H$_2$C(Br)–Br•••Br$^-$ short contacts...
referred to XB insofar as \(d(\text{Br} \cdots \text{Br}) = 3.3137(8) \text{ Å}\) is less than Rowland’s \(2R_{\text{vdW}}(\text{Br}) = 3.74 \text{ Å}\), and \(\angle(\text{C–Br} \cdots \text{Br})\) is 169.4(2)°. These values agree well with both geometrical IUPAC criteria\(^{51}\) for XB.

In 3a•CH\(_2\)Cl\(_2\), 3a•CH\(_2\)Br\(_2\), 4•CH\(_2\)Cl\(_2\), and 4•CH\(_2\)Br\(_2\), apart from XBs numerous N–H•••X, C–H•••X, N–H•••X–Pd, and C–H•••X–Pd (X = Cl, Br) HB’s were identified (see Supporting information).

**Figure 3.** Packing of dihalomethane molecules and halide anions in 3a•CH\(_2\)Cl\(_2\) (a), 3a•CH\(_2\)Br\(_2\) (b), 4•CH\(_2\)Cl\(_2\) (c), and 4•CH\(_2\)Br\(_2\) (d). Thermal ellipsoids are given at the 50% probability level.
a1
**Figure 4.** Two types of isostructural fragments in $3a \cdot CH_2Cl_2$ (a1, a2) and analogous fragments in $3a \cdot CH_2Br_2$ (b), $4 \cdot CH_2Br_2$ (c), and $4 \cdot CH_2Cl_2$ (d). Cyclohexyl rings were omitted for clarity. Thermal ellipsoids are given at the 50% probability level.

![Diagram showing two types of isostructural fragments](image)

**Figure 5.** One of the heterotetrameric clusters in $3a \cdot CH_2Cl_2$ (a) and the analogous clusters in $3a \cdot CH_2Br_2$ (b), and $4 \cdot CH_2Br_2$ (c). Cyclohexyl rings were omitted for clarity. Thermal ellipsoids are given at the 50% probability level.

Noteworthy that in $3a \cdot CH_2Cl_2$, $3a \cdot CH_2Br_2$, and $4 \cdot CH_2Cl_2$, we observed the heterotetrameric clusters (Figure 5) that consist of two complex cations and two solvent molecules with two types of the $X_2C(H)\cdots H \cdots X \cdots Pt$ (X = Cl, Br) HB’s. Electrostatic repulsion between the negatively charged halide ligands is shielded by two solvent molecules. Similar clusters were previously reported by us, and these species contain two neutral chloride platinum(II) complexes and two dihalomethane molecules, simultaneously linked by two $X_2C(H)\cdots H \cdots Cl \cdots Pt$ HB’s and two $H_2C(X)\cdots X \cdots Cl \cdots Pt$ (X = Cl, Br) XB’s.

\textsuperscript{*}The strength of these weak interactions (in kcal/mol) has been defined according to the procedures proposed by Espinosa et al. \( (E_{\text{int}}^a = -V(r)/2) \)\textsuperscript{56} and Vener et al. \( (E_{\text{int}}^b = 0.429G(r)) \)\textsuperscript{57} these approaches considered explore linear relationships between potential energy \( V(r) \) and Lagrangian kinetic energy \( G(r) \) densities at the bond critical points and energies of appropriate contacts.

\textsuperscript{**}“Comparison” is the sum of Rowland’s vdW radii and the classicXB angle.

**Theoretical considerations.** Inspection of the crystallographic data for dihalo methane solvates \( \text{3a} \end{array} \text{•CH}_2\text{Cl}_2 \), \( \text{3a} \end{array} \text{•CH}_2\text{Br}_2 \), and \( \text{4•CH}_2\text{Br}_2 \) suggests the availability of Cl\textbullet\textbullet\textbullet Cl\textsuperscript{–} and Br\textbullet\textbullet\textbullet Cl\textsuperscript{–} XB contacts and along with the presence different types of HBs. To confirm the existence of these weak XB interactions from theoretical viewpoint and evaluate their energies, we performed DFT calculations followed by Bader’s QTAIM analysis.\textsuperscript{58} We have successfully used this approach upon studies of non-covalent interactions and properties of coordination bonds in various transition metal complexes.\textsuperscript{36,40,59-65} The model systems were isolated from the experimental X-ray data as three large clusters (cis-[PdCl(CNCy)] \( \text{C(NHCy)=NHCH}_2\text{H}_2\text{Me}_2\text{NH}_2 \})_6\textbullet\textsuperscript{Cl}•(\text{CH}_2\text{X}_2)_2 \) (\( \text{X} = \text{Cl} \), two types, see
Figure 2, a–b; X = Br, c), which include all types of short contacts. Results of QTAIM analysis are summarized in Table 4 (XBs) and Table SV2 (HBs).

Table 4. Values of the density of all electrons – ρ(r), Laplacian of electron density – ∇^2 ρ(r), energy density – Hb, potential energy density – V(r), and Lagrangian kinetic energy – G(r) (Hartree) at the bond critical points (3, –1), corresponding to the H2C(X)–X•••Cl (X = Cl, Br) XBs.

* The strength of these weak interactions (in kcal/mol) has been defined according to the procedures proposed by Espinosa et al. (E_{int}^a = –V(r)/2) and Vener et al. (E_{int}^b = 0.429G(r)), these approaches considered explore linear relationships between potential energy V(r) and Lagrangian kinetic energy G(r) densities at the bond critical points and energies of appropriate contacts.

** Type of calculations: exp. – single point calculations based on the experimental X-ray geometries for the large clusters (cis-[PdX(CNCy)2[NHCy]=NHCy2H2Me2NH2])_8•(X)_{2•}(CH2X)2, free – single point calculations based on the experimental X-ray geometries for
The QTAIM analysis allows the verification of several bond critical points (BCP’s) (3, –1) for XBs C–X•••X (X = Cl, Br) (Table 4) and different HB’s (Table SV2). The low magnitude of the electron density, positive values of the Laplacian, and very close to zero energy density in these BCP’s are typical for non-covalent interactions. The relation \(-G(r)/V(r) \geq 1\) for all BCP’s listed in Tables 4 and SV2, and points out that the nature of these interactions is purely non-covalent.\(^{66}\) The small values of the Wiberg bond indices for C–X•••X contacts in the optimized structures (viz. 0.08–0.18) computed by using the natural bond orbital (NBO) partitioning scheme additionally confirm the electrostatic nature of these non-covalent interactions.
Figure 6. Experimental (left) and optimized (right) structures of the (X–)•(CH₂X₂) clusters, length unit – Å.

We attempted to estimate the effect of short-range environment and crystal packing on the energies of XBs in the studied systems. For these purposes we isolated the small clusters (Cl–)(CH₂Cl₂) (Figure 6, a), (Cl–)(CH₂Br₂) (b), and (Br–)(CH₂Br₂) (d) from the experimental X-ray geometries of 3a•CH₂Cl₂, 3a•CH₂Br₂, and 4•CH₂Br₂, respectively, and carried out single point calculations and QTAIM analysis (in this case only short-range environment effect is excluded from the consideration). Then we performed geometry optimization procedure followed by the single point calculations and QTAIM analysis (in that case both effects are not taking into account). For the cluster (Br–)(CH₂Cl₂), the starting (Cl–)(CH₂Cl₂) geometry followed by the Cl–/Br– exchange was used (Figure 6, c). Our results are presented in Table 4.
(“free” for the starting experimental geometries, “opt.” for the optimized geometries). It is clear that short-range environment virtually does not affect the energies of XBs, but the influence of crystal packing is much more significant. Indeed, geometry optimization leads to shortening of the Br•••Cl, Cl•••Cl, and Br•••Br contacts by 0.250–0.313 Å and to their approximately two-fold strengthening. Noteworthy that the optimized structures $a–d$ exhibit similar structural motifs. The contour line diagrams of the Laplacian distribution $\nabla^2 \rho(r)$, bond paths and selected zero-flux surfaces for the optimized $(X^-)\cdot(CH_2X_2)$ clusters are shown in Figure 7. To visualize XBs in the studied systems, reduced density gradient (RDG) analysis was carried out. The RDG isosurfaces reveal the presence of $H_2C(X)–X\cdots X^- (X = Cl, Br)$ non-covalent interactions in optimized structures of $(Cl^-)\cdot(CH_2Cl_2)$, $(Cl^-)\cdot(CH_2Br_2)$, $(Br^-)\cdot(CH_2Cl_2)$, and $(Br^-)\cdot(CH_2Br_2)$.

Figure 7. Contour line diagrams of the Laplacian distribution $\nabla^2 \rho(r)$, bond paths, and selected zero-flux surfaces (left) and RDG isosurfaces referring to the XBs (right) for the optimized structures of $(Cl^-)\cdot(CH_2Cl_2)$, $(Cl^-)\cdot(CH_2Br_2)$, $(Br^-)\cdot(CH_2Cl_2)$, and $(Br^-)\cdot(CH_2Br_2)$. Bond critical
points (3, –1) are shown in blue, nuclear critical points (3, –3) – in pale brown. Length units – Å, RDG isosurface values are given in Hartree.

We additionally evaluated the magnitude of intermolecular interaction energies in the XB linked clusters (Cl\(^–\))•(CH\(_2\)Cl\(_2\)), (Cl\(^–\))•(CH\(_2\)Br\(_2\)), (Br\(^–\))•(CH\(_2\)Cl\(_2\)), and (Br\(^–\))•(CH\(_2\)Br\(_2\)) by supermolecule method using both coupled cluster approach and second order Møller–Plesset perturbation theory at the CCSD(T)/aug-cc-pVDZ//M06/DZP-DKH and MP2/aug-cc-pVDZ//M06/DZP-DKH computational levels. The obtained values of intermolecular interaction energies are higher than those obtained from QTAIM analysis, but lower than calculated vertical dissociation energies at the M06/aug-cc-pVDZ//M06/DZP-DKH level of theory (Table 5). The intermolecular interaction energy turns larger with the increase of σ-hole on XB donor and the polarizability decrease of the XB acceptors along the following series H\(_2\)C(Cl)–Cl\(\cdots\)Br\(^–\) < H\(_2\)C(Cl)–Cl\(\cdots\)Cl\(^–\) < H\(_2\)C(Br)–Br\(\cdots\)Br\(^–\) < H\(_2\)C(Br)–Br\(\cdots\)Cl\(^–\).

Table 5. The calculated vertical dissociation energies \(\Delta E_1\) (CCSD(T)/aug-cc-pVDZ//M06/DZP-DKH), \(\Delta E_2\) (MP2/aug-cc-pVDZ//M06/DZP-DKH), and \(\Delta E_3\) (M06/aug-cc-pVDZ//M06/DZP-DKH) of XB linked optimized clusters (Cl\(^–\))•(CH\(_2\)Cl\(_2\)), (Cl\(^–\))•(CH\(_2\)Br\(_2\)), (Br\(^–\))•(CH\(_2\)Cl\(_2\)), and (Br\(^–\))•(CH\(_2\)Br\(_2\)) (in kcal/mol).

We have defined energies for all these contacts according to the procedures proposed by Espinosa et al.\textsuperscript{56} and Vener et al.,\textsuperscript{57} and one can state that: (i) strengths of XBs in these systems varies from 1.9 to 2.8 kcal/mol; (ii) the energies of C–X⋯Cl− XBs for X = Br in all cases are higher than those for X = Cl by 13–47%. This observation agrees well with the previously reported\textsuperscript{17} and calculated (Table 1) electrostatic potentials on the halogen atoms in CH\textsubscript{2}Br\textsubscript{2} and CH\textsubscript{2}Cl\textsubscript{2}; (iii) the strongest N–H⋯Cl− HB’s may be classified as moderate force contacts (> 4 kcal/mol) mainly due to electrostatics following the classification of Jeffrey (‘‘strong’’ H-bonds: 40–15 kcal/mol, ‘‘moderate’’ H-bonds: 15–4 kcal/mol, ‘‘weak’’ H-bonds: <4 kcal/mol).\textsuperscript{68} Thus, results of our theoretical calculations confirm the presence and provide the energies of the previously unreported H\textsubscript{2}C(X)–X⋯X− (X = Cl, Br) XBs involving uncomplexed halides. Results of our calculations can be compared with the data obtained at the MP2/aug-cc-pVDZ level of theory for XBs in TEMPO•CH\textsubscript{2}Cl\textsubscript{2} (2.5 kcal/mol) and TEMPO•CH\textsubscript{2}Br\textsubscript{2} (3.7 kcal/mol) supramolecular clusters.\textsuperscript{17} The larger evaluated energies of XBs in cases of anions as XB acceptors (3.4 and 4.2 kcal/mol for CH\textsubscript{2}Cl\textsubscript{2} as XB donor; 8.9 and 10.0 kcal/mol for CH\textsubscript{2}Br\textsubscript{2} as XB donor) can be explained by charge reasons.

**Verification of H\textsubscript{2}C(X)–X⋯X− (X = Cl, Br) XBs in other systems.** We processed available CCDC data and found nine structures exhibiting H\textsubscript{2}C(Cl)–Cl⋯Cl− XBs (Table 6) and four structures with H\textsubscript{2}C(Cl)–Cl⋯Br− XBs (Table 7) accordingly to their geometric parameters; all these contacts were overlooked in the corresponding reports. The H\textsubscript{2}C(Br)–Br⋯X− XBs were not found although the H\textsubscript{2}C(Br)–Br⋯Cl–Pt XBs with metal-bound chloride were previously reported by us\textsuperscript{36} and the H\textsubscript{2}C(Br)–Br⋯Br–C XBs were observed in the crystalline dibromomethane.\textsuperscript{69,70} Remarkable that XB in 3a•CH\textsubscript{2}Cl\textsubscript{2} is the shortest chlorine⋯chlorine separation involving dihalomethane so far recognized.

Concluding Remarks

A series of the \(\text{cis}[-\text{PdX(CNCy)}\{\text{C(NHCy)}=\text{NHC}_6\text{H}_2\text{Me}_2\text{NH}_2\}]\cdot\text{CH}_2\text{X}_2 \ (X = \text{Cl, Br})\) associates with the dihalomethanes were characterized by XRD. In the structures of \(\text{3a} \cdot \text{CH}_2\text{Cl}_2\), \(\text{3a} \cdot \text{CH}_2\text{Br}_2\), and \(\text{4} \cdot \text{CH}_2\text{Br}_2\), we detected the previously unreported \(\text{H}_2\text{C}(X)\cdots X \cdots X^- \ (X = \text{Cl, Br})\) contacts with uncomplexed halides that fulfill the IUPAC criteria for the halogen bonding. Results of Bader’s QTAIM analysis (M06/DZP-DKH level of theory) reveal that estimated strength of these XBs varies from 1.9 to 2.8 kcal/mol and that these contacts are actually non-covalent; the crystal packing significantly affects the lengths and energies of XBs.

Our processing of the available CCDC data allowed the recognition of some more \(\text{H}_2\text{C}(\text{Cl})\cdots \text{Cl} \cdots X^- \ (X = \text{Cl, Br})\) halogen bonds, but no \(\text{H}_2\text{C}(\text{Br})\cdots \text{Br} \cdots X^- \ (X = \text{Cl, Br})\) XBs were found. All contacts presented in \textbf{Tables 6} and \textbf{7} were overlooked in the corresponding papers. It is clear that the XB in \(\text{3a} \cdot \text{CH}_2\text{Cl}_2\) is the shortest chlorine\cdots chlorine separation involving dihalomethane so far recognized.

The results reported in this work can be used as starting point for further studies of XBs in dihalomethane solutions, where they may be sufficiently strong to contribute, along with H-bonding, to the overall solvation. We hope that our observation will be beneficial for both crystal
engineering and physical chemistry communities because it expands the arsenal of supramolecular assembly and contributes to the understanding of solvation with dihalomethanes.

**Experimental section**

**Materials and Instrumentation.** Solvents, PdCl₂, and cyclohexyl isocyanide were obtained from commercial sources and used as received, whereas CH₂Cl₂ was purified by the conventional distillation over calcium chloride. 3,4-Dimethylbenzene-1,2-diamine was synthesized from 3,4-dimethylaniline (synthetic procedure can be found in Supporting Information). Complex 3a was synthesized by the reported procedure and 4 was synthesized from 3a by metathesis with KBr in acetone. C, H, and N elemental analyses were carried out on a Euro EA 3028HT CHNS/O analyzer. Mass-spectra were obtained on a Bruker microTOF spectrometer equipped with electrospray ionization (ESI) source; MeOH was used as the solvent. The instrument was operated both at positive and negative ion modes using m/z range of 50–3000. The capillary voltage of the ion source was set at –4500 V (ESI⁺) or 3500 V (ESI⁻) and the capillary exit at ±(70–150) V. The nebulizer gas pressure was 0.4 bar and drying gas flow 4.0 L/min. The NMR spectra were recorded on Bruker AVANCE III 400 spectrometer at ambient temperature in CDCl₃ (at 400, and 100 MHz for ^1^H and ^13^C{^1^H} NMR spectra, respectively). Chemical shifts are given in δ-values [ppm] referenced to the residual signals of non-deuterated solvent (CHCl₃): δ 7.26 (^1^H) and 77.2 (^13^C). ^1^H and ^13^C{^1^H} NMR data assignment for 4 produced by using 2D (^1^H, ^13^C-HMOC/HSQC and ^1^H, ^13^C-HMBC) NMR correlation experiments.

**Synthesis, crystallization, and structure refinement.** Synthesis of 4. Solid KBr (480 mg, 4 mmol) was added to a suspension of 3a (53 mg, 0.1 mmol) in acetone (4 mL) at 20–25 °C
and the reaction mixture was stirred at RT for 1 d. The formed suspension was evaporated at 40–45 °C under normal pressure and the product was extracted with three 2-mL portions of CH$_2$Cl$_2$. The resulting bright yellow solution was filtered off to remove some insoluble material, the filtrate was evaporated at RT to dryness, and thus formed solid was dried in air at 20–25 °C.

4•CH$_2$Cl$_2$. Yield 93%. Calc. for C$_{23}$H$_{36}$N$_4$Br$_2$Cl$_2$Pd: C, 39.15; H, 5.14; N, 7.94. Found: C, 39.30; H, 5.17; N, 7.99. HRESI$^+$-MS (70 V, MeOH): calc. for C$_{23}$H$_{34}$N$_4$BrPd $^+$ 539.0996, found m/z 539.1004 [M – Br $^+$]. $^1$H NMR (CDCl$_3$, δ): 0.86–1.91 (20Н, m, CH$_2$), 2.08 (3Н, s, CH$_3$), 2.18 (3Н, s, CH$_3$), 3.67–3.70 (1Н, m, CH), 3.83–3.86 (1Н, m, CH), 5.30 (2H, s, CH$_2$Cl$_2$), 6.71 (1Н, s, H$_{\text{Ar}}$), 6.91 (1Н, s, H$_{\text{Ar}}$), 9.24–9.27 (1H, m, C$_{\text{carbene}}$–N$\equiv$H–Cy), 10.66 (1Н, s, NH). $^{13}$C{$^1$H} NMR (CDCl$_3$, δ): 19.03 (CH$_3$), 19.07 (CH$_3$), 22.58 (2CH$_2$), 24.47 (CH$_2$), 24.71 (3CH$_2$), 31.77 (2CH$_2$), 33.88 (2CH$_2$), 53.39 (CH$_2$Cl$_2$), 55.68 (CH), 59.17 (CH), 122.15(CH$_{\text{Ar}}$), 122.77 (CH$_{\text{Ar}}$), 123.61 (C≡N), 124.55(CH$_{\text{Ar}}$), 133.03 (CH$_{\text{Ar}}$), 133.69 (CH$_{\text{Ar}}$), 135.38 (CH$_{\text{Ar}}$), 179.06 (C$_{\text{carbene}}$).

Crystals of 3a•CH$_2$Cl$_2$, 3a•CH$_2$Br$_2$, 4•CH$_2$Cl$_2$, and 4•CH$_2$Br$_2$ were obtained upon slow evaporation of a solution of 3a or 4•CH$_2$Cl$_2$ in CH$_2$Cl$_2$ and CH$_2$Br$_2$, respectively, in air at RT. Details of structure solutions and refinements can be found in SI.

**Computational Details.** Unless otherwise indicated, the single point calculations and full geometry optimization have been carried out at the DFT level of theory using the M06 functional$^{73}$ (this functional describes reasonably weak dispersion forces and non-covalent interactions$^{74,75}$) with the help of Gaussian-09$^{76}$ program package. The Douglas–Kroll–Hess 2$^{nd}$ order scalar relativistic calculations requested relativistic core Hamiltonian were carried out.
using DZP-DKH basis sets\textsuperscript{77-83} for all atoms based on the experimentally obtained X-ray geometries \((\text{cis-[PdCl(CNCy)}{\text{C(NHCy)=NH}}\text{C}_6\text{H}_2\text{Me}_2\text{NH}_2]})_6\text{•}(\text{Cl})_2\text{•}(\text{CH}_2\text{Cl})_2\text{ (two types)}, \text{(cis-[PdCl(CNCy)}{\text{C(NHCy)=NH}}\text{C}_6\text{H}_2\text{Me}_2\text{NH}_2]})_6\text{•}(\text{Br})_2\text{•}(\text{CH}_2\text{Br})_2\text{, (Cl)}\text{•}(\text{CH}_2\text{Cl})_2 \text{ (two types), and (Cl)}\text{•}(\text{CH}_2\text{Br})_2\text{)) or optimized equilibrium structures ((Cl)}\text{•}(\text{CH}_2\text{Cl})_2 \text{ (two types) and (Cl)}\text{•}(\text{CH}_2\text{Br})_2\text{)}. No symmetry restrictions have been applied during the geometry optimization. The Hessian matrix was calculated analytically for optimized structures to prove the location of correct minima (no imaginary frequencies). The topological analysis of the electron density distribution with the help of the atoms in molecules (QTAIM) method developed by Bader\textsuperscript{84} has been performed by using the Multiwfn program (version 3.3.4).\textsuperscript{85}

SYNOPSIS

The weakest $\sigma$-hole dichloromethane and dibromomethane still form XB with chloride in bromide in the solvates of acyclic diaminocarbene palladium(II) complex used as a scaffold. The estimated bonding energies of the $H_2C(X)\cdots X^- X$ non-covalent interactions is in the 1.9–2.8 kcal/mol range.
