Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

Abstract

Purpose: This longitudinal study examined the development of prelinguistic skills, and continuity of communication and language from prelinguistic stage to school age.

Method: Prelinguistic communication of 427 Finnish children was followed repeatedly from 6 to 18 months of age ($n=203-322$ at ages 6, 9, 12, 15, and 18 months), and its associations with language ability at ages 2;0 ($n=104$), 3;0 ($n=112$), 4;7 ($n=253$), 5;3 ($n=102$) and 7;9 ($n=236$) were examined using latent growth curve modeling.

Results: Prelinguistic development across several skills emerged as a rather stable intra-individual characteristic during the first two years of life. Continuity from prelinguistic development to later language ability was indicated. The common level and growth of prelinguistic skills were significant predictors of language ability between ages 2;0-7;9, the percentage explained varying between 10.5-53.3%. A slow pace of development across multiple skills, in particular, led to weaker language skills.

Conclusions: The results support the idea of a developmental continuum from prelinguistic to linguistic ability, and the dimensional view of language ability, by indicating that individual variations in early communication skills show consistency that extends beyond the toddler years. Our results also advocate developmental surveillance of early communication by emphasizing the significance of growth in predicting language development.

Keywords: communication, language, development

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

Continuity from prelinguistic communication to later language ability: a follow-up study from infancy to early school age

The development of communication skills starts long before children are able to use language as their primary means of communication. The prelinguistic stage refers to the period during which children use mainly nonverbal means of communication, and spans intentional preverbal communication and the transition to first words (Watt, Wetherby, & Shumway, 2006). The first two years of life is an important period in the development of these early communication skills. The way infants communicate prelinguistically is thought to form a developmental continuum with later, more language-based, communication (Bruner, 1983). Accordingly, Bates (2004) and Rescorla (2009, 2013) have suggested that several interrelated but distinct early socio-cognitive skills serve as building blocks for later language. That is, language emerges from the interactions of these early socio-cognitive processes (Bates, 2004), and differences in language ability stem, in part, from the differential endowment of these language-subserving skills (Rescorla, 2009).

These early socio-cognitive skills (i.e., prelinguistic means of communication) include joint attention, gestures, early vocalizations, first words, language comprehension, and play (Watt et al., 2006). Although these skills and their connections to later language outcome have been rather extensively studied (for a review, see McCathren, Warren, & Yoder, 1996), studies examining several of these skills together, their co-development over time and the implications that this co-development has on later language, are lacking. Thus, it is not possible to ascertain whether it is the general level or pace of early communication development (i.e., the variation that is shared across skills) that is predictive of later language ability, or whether a specific skill, or a combination of skills, at a specific age makes a unique contribution to language development over and above that of the general level. The present study utilizes a longitudinal design to address how prelinguistic communication skills, assessed repeatedly with a multifaceted parental screener covering relevant areas of social, speech, and symbolic skills, develop during the first two years of life. The connections between this development and that of later

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

language and communication are followed up to school age.

The development of prelinguistic skills

Language and communication development is characterized by substantial inter- and intra-individual variation in the acquisition of different skills. However, despite this variation, both continuity (i.e., group-mean-level consistency) and stability (i.e., consistency in the relative standing of individuals over time) in language development have been reported (Bornstein, Hahn, Putnick, Suwalsky, 2013; Bornstein & Putnick, 2012; Fenson et al., 1994; Thal, Bates, Goodman, & Jahn-Samilo, 1997). The dimensional view of language ability (Rescorla, 2009, 2013) argues for the stability of individual differences in language skills by suggesting that the rank order of children is partly determined by differential endowment. According to Rescorla (2009, 2013) this endowment, that is, a spectrum of language ability which she compares to that of intelligence, derives from variation in several language-sub-serving socio-cognitive skills and is, at least partly, constitutionally based. These skills, such as auditory perception and processing, verbal working memory, and joint reference are assumed to form the base from which prelinguistic communication and later, language ability develops (Bates, 2004; Rescorla, 2013).

Research on stability in the development of language and communication has tended to focus more on older ages. For example, according to Bornstein and colleagues (2012, 2013), when multiple domains, measures, and sources are used across age, child language emerges as a stable characteristic of individual differences. The development of communication in the prelinguistic period has been less extensively studied. The developmental sequences of separate prelinguistic skills such as gestures (Bates & Dick 2002) and joint attention (Carpenter, Nagell, & Tomasello, 1998) have been studied, but several prelinguistic skills have been included in the same analysis in only a few studies, while even fewer have tracked the co-development of these skills in the prelinguistic period.

The few studies that have examined multiple prelinguistic skills simultaneously have reported significant correlations between measures of different skills (e.g., Laakso, Poikkeus, Katajamäki, &

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 Lyytinen, 1999; Watt, et al., 2006), indicating that these measures partially tap the same underlying
3
4 functions (i.e. language endowment). For example, in Laakso et al. (1999) parental report on gestures
5
6 and concurrently observed joint attention correlated significantly ($r = .21-.26$) at age 14 months. Watt et
7
8 al. (2006) explored the concurrent correlations of several prelinguistic skills and reported that gestures (r
9
10 $= .29-.46$) and joint attention ($r = .29-.47$) were significantly correlated with most of the other measures,
11
12 especially early in the second year of life (a total of 22/36 correlations were significant, $r = .01-.61$ at 14
13
14 months, and 11/36, $r = .00-.75$ at 20 months).
15
16
17

18
19 Darrah, Hodge, Magill-Evans, and Kembhavi (2003), Reilly et al. (2006), Watt et al. (2006), and
20
21 Wetherby, Allen, Cleary, Kublin, and Goldstein (2002) have examined the development of the social,
22
23 speech, and symbolic skills of children using the Infant-Toddler Checklist (ITC) or the Behavioral
24
25 Sample of the Communication and Symbolic Behavior Scales Developmental Profile (CSBS DP,
26
27 Wetherby & Prizant, 2002). These studies have all reported significant longitudinal correlations between
28
29 assessments of joint attention, gestures, vocalizations, first words, and comprehension in the
30
31 prelinguistic period (13-21 months $r = .46-.55$ for the total score in Darrah et al., 2003; 8-12 months β
32
33 $= .56$ for the total score in Reilly et al, 2006; 14-20 months, $r = .39-.59$ in separate skills in Watt et al.,
34
35 2006; 13-20 months, $r = .77-.89$ for the different composites, and $r = .85-.91$ for the total score in
36
37 Wetherby et al., 2002). These correlations indicate stability in individual differences in the development
38
39 of these skills over time whereas concurrent reports on increases in raw scores indicate fast growth in
40
41 these skills (Watt et al., 2006; Wetherby et al., 2002).
42
43
44
45
46

47 **General level and pace of development or skill- and age-specific associations?**

48
49 It has been shown that a major predictor of communication and language status at a given age is
50
51 the level of skills at an earlier age, both in the prelinguistic stage (Reilly et al., 2006, 2007) and during
52
53 later language development (Bornstein & Putnick, 2012). However, it has also been suggested that the
54
55 pace of development, rather than the level at any given age, might be more predictive of later
56
57 development (e.g. Rowe, Raudenbush, & Goldin-Meadow, 2012). This view has received support from
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 studies examining vocabulary development (Rescorla, Mirak, & Singh, 2000), and early precursors of
3
4 literacy (Lyytinen et al., 2006). According to Rowe et al. (2012), it is plausible that “the rates of growth
5
6 likely contain more information about the child’s language acquisition potential than their ability at one
7
8 point in time” (p. 510). This could be the case, especially with respect to early communication
9
10 development, where growth depends also on the acquisition of new skills as well as augmenting existing
11
12 skills (Reilly et al., 2006).
13

14
15
16 Another relevant question is whether it is the general (i.e., common) level or growth of
17
18 prelinguistic development across several skills or a specific skill at a specific age that best predicts later
19
20 language ability. Research has established links between several early socio-cognitive and prelinguistic
21
22 communication skills and later language ability: for example, gaze following (Brooks & Meltzoff,
23
24 2008), and other forms of joint attention (Beuker, Rommelse, Donders, & Buitelaar, 2013), gestures
25
26 (Colonnesi, Stams, Koster, & Noom, 2010), deferred imitation (Heimann, et al., 2006), verbal
27
28 comprehension and symbolic play (Bruce, Kornfält, Radeborg, Hansson, & Nettelbladt, 2003), and
29
30 frequency of intentional communication and reciprocity (Paavola, Kemppinen, Kumpulainen, Moilanen,
31
32 & Ebeling, 2006). However, the comparison of studies is difficult, as their measures, ages and
33
34 methodology vary considerably. In addition, multiple prelinguistic skills have been rarely addressed in
35
36 the same study.
37
38
39
40
41

42 The results reported thus far suggest that the proportion of shared variance between the different
43
44 prelinguistic measures is large relative to the unique contribution of single skills (Watt et al., 2006;
45
46 Wetherby et al., 2002). For example in the studies by Wetherby and colleagues (2002; Watt et al.,
47
48 2006), the joint contribution of gaze following, joint attention, gestures, vocalizations, first words,
49
50 comprehension, and play was large relative to the unique contribution of any of these skills for the
51
52 predicted variance. This led the authors to conclude that judgments about the relative importance of any
53
54 particular skill in predicting language outcome should be guarded, and that using an array of
55
56 prelinguistic measures strengthens their predictive value.

However, despite the large shared variance, the studies by Wetherby and colleagues on the different composites of the ITC have found specific associations between the social and symbolic composites and receptive language ($pr = .23-.62$), the speech composite and expressive language ($pr = .17-.59$, Wetherby et al., 2002), and the social composite and later autism spectrum disorder (Wetherby, Brosnan-Maddox, Peace, & Newton, 2008). Heimann et al. (2006) tracked the development of deferred imitation (early memory) and joint attention between ages 6-14 months and found that deferred imitation at 9 months was the single strongest predictor of gestures ($\beta = .53$) at age 14 months. In addition, Bruce et al. (2003) reported significant unique contributions of verbal comprehension ($r = -.58$) and symbolic play ($r = -.40$) at age 18 months to language difficulties at age 4;5. However, despite a rather comprehensive assessment of language at the follow-up, they reported the outcome results as frequency of difficulties, thus rendering generalization to typical development difficult. In Lyytinen, Poikkeus, Laakso, Eklund, and Lyytinen (2001), symbolic play at 14 months of age was found to correlate significantly ($r = .28-.39$) with later receptive language skills in typically developing children. However, when early comprehension was controlled for in regression models, symbolic play did not uniquely predict language outcome ($\beta = .13$). Similarly, Salley, Panneton and Colombo (2013) found that visual attention and joint attention made unique contributions to later vocabulary size ($\beta = 0.278$), but when baseline communication was controlled for, joint attention was no longer a significant predictor ($\beta = 0.093$). Thus, the results on the unique predictive ability of different prelinguistic skills remain inconclusive.

The predictive relations of different prelinguistic skills with language development have also been found to show age-specificity. Watt et al. (2006) studied the different variables of the CSBS DP and found that the predictive relations varied according to age: Early in the second year of life, specific predictive associations were found between gestures and receptive language, and joint attention and expressive language. Late in the second year, inventory of consonants contributed uniquely to expressive language. Comprehension was predictive of later receptive and expressive language

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

throughout the second year. Others (Brooks & Meltzoff, 2008; Heimann et al., 2006; Rose, Feldman, Jankowski, & Van Rossem, 2008) have also suggested that the age at which early skills are assessed might affect the way they relate to later abilities, that is, the predictive power of a certain skill might vary depending on whether the skill is just emerging or already more established.

Goals of the present study

This study addresses the question of continuity and stability both within the prelinguistic period and from the prelinguistic period to linguistic development. We examined the development of early communication skills by repeatedly following, during the first two years of life, several of the relevant developmental areas suggested by previous research. In addition, we explored the longitudinal associations of this early development with later language ability. Following the premises of the dimensional view of language (Rescorla, 2013) and the suggestions of Bornstein and Putnick (2012) and Conti-Ramsden and Durkin (2012), a multiage, multidomain, multimeasure, and multisource approach was adopted in the follow-up procedures of the present study. The complex nature of language requires that both multiple dimensions of language and measures of working memory be used in the assessment (Conti-Ramsden & Durkin, 2012). The associations between prelinguistic development and subsequent language outcomes were studied in separate but largely overlapping subsamples at five consecutive time points (at age 2;3, 2;7, 3;3, 3;7, and first grade, mean age 7;9, range 7;2 – 8;4). Three areas of language development (expressive, receptive, communicative/pragmatic), along with verbal working memory, were explored using several different measures, including both parental report and psychometric testing.

Specifically, we asked:

1. How is the development of prelinguistic communication skills depicted when three relevant areas of development (social, speech, symbolic) are assessed longitudinally between 6 and 18 months of age? In particular, we explored the stability of individual differences over time, and whether development in these three areas is mainly overlapping (i.e., can be depicted by a model of common level and growth)

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 or distinct (i.e., skill-specificity), and whether the course of development shows age-related differences
3
4 (i.e., age-specificity). Based on previous findings on early communication skills (Laakso et al., 1999)
5
6 and the ITC (Watt et al., 2006; Wetherby et al., 2002), we expected the three studied areas to show
7
8 significant shared variance and also, to some extent, skill- and age-specific variance. In addition, we
9
10 expected to find stability in development over time.
11
12

- 13
14 2. Which aspects of early development (i.e., common level and growth or skill- or age-specific features)
15
16 best predict later language ability? In accordance with the dimensional view (Rescorla, 2009, 2013),
17
18 and earlier findings (e.g., Bornstein et al., 2013), we expected to find indications of continuity and
19
20 stability on the aggregate level (i.e., common level and growth predicting later abilities). Based on the
21
22 findings of Wetherby and colleagues (2002; Watt et al., 2006) in somewhat older samples, we
23
24 hypothesized that social and symbolic skills would show more predictive power early on in
25
26 development, whereas the role of speech skills might be more pronounced later on.
27
28
29

30 **Method**

31
32 Brief summaries of the methods follow; for a more detailed description of the participants, procedures,
33
34 and measures, see the online Supporting Material.
35
36

37 **Participants and procedure**

38
39 The participants of the present study represent subsets of a community-based sample collected in
40
41 a longitudinal study of early language and communication development conducted between the ages of
42
43 6 months and 8 years (see Määttä, Laakso, Tolvanen, Ahonen & Aro, 2012, 2014). Altogether, 508
44
45 children (50.2 % boys, 49.8 % girls) aged 6 to 24 months participated in the study. All of the families
46
47 were Caucasian, and all of the children spoke Finnish as their native language. At the initial assessment,
48
49 mothers' mean age was 29.8 years ($SD = 5.4$), and fathers' 32.1 years ($SD = 6.3$). Educational
50
51 attainment was assessed with a 7-point scale ranging from no vocational education (0) to a higher-level
52
53 university degree (6). The mean educational level was 3.9 ($SD = 2.0$) for mothers and 3.6 ($SD = 2.0$) for
54
55 fathers.
56
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 The early questionnaire (ITC) data were collected repeatedly every three months until the
3
4 children were 24 months of age. The total number of questionnaires filled in by the parents depended on
5
6 the age of their child at recruitment and on how many of the subsequent forms they completed. In the
7
8 present study we used the data gathered on the children across ages 6 – 18 months. This yielded a total
9
10 sample of 427 children ($n = 229$ at 6 months, $n = 203$ at 9 months, $n = 322$ at 12 months, $n = 305$ at 15
11
12 months, and $n = 279$ at 18 months of age). Of these 427 children 25.8 % had data from all five data
13
14 points, 9.6 % from four, 29.0 % from three, 23.4 % from two and 12.2 % from one data point. The last
15
16 two measurements of the early data, collected at 21 and 24 months, were excluded from the analyses
17
18 due to skewed and kurtic distributions (ceiling effect).
19
20
21
22

23 Subgroups of the original participants were followed after the ITC data collection phase at the
24
25 age of 2, 3, 4;7, and 5;3 years, and in the spring term of first grade (mean age 7;9, range 7;2-8;4). The
26
27 numbers of participants are described in Figure 1, subsample differences in the ITC scores in Table
28
29 SM1, and the demographic data of the different subsamples along with information on Finnish families
30
31 and family services in the online Supporting Material and Table SM2. In the follow-ups at ages 2, 3, and
32
33 5;3, we were not able to collect information from all the families, owing to time and resource
34
35 limitations. Thus, the subsamples were constructed so as to ensure that a sufficient number of at-risk
36
37 children would participate. At-risk status was defined as slow communication development in ITC at
38
39 ages 12, 15 and 18 months following the criteria suggested by Wetherby & Prizant (2002; follow-ups at
40
41 ages 2 and 3 years) or as a high score (90th percentile) in a parent report symptom questionnaire at age
42
43 4;7 (follow-up at age 5;3). In the follow-ups at age 4;7 and first grade, all the originally participating
44
45 families, excluding those who had declined to participate in further follow-ups in the previous data
46
47 collection phases, were attempted to contact. For the families that were not reached, we were unable to
48
49 find a valid address.

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3
4 At age 2, a small subset of families ($n = 143$) was invited to fill in the MacArthur-Bates
5
6 Communicative Inventories (MBCDI; Fenson et al., 1994; Lyytinen, 1999). The participants included
7
8 65 children who were identified as being at risk based on their scores in the ITC, using the norms and
9
10 10th percentile cut-off reported by the original authors (Wetherby & Prizant, 2002). These children
11
12 performed either in the lowest 10 percent in the social or symbolic composites at 12 or 15 months of age
13
14 or within the lowest 10 percent in the speech composite at 15 or 18 months of age. The rest of the
15
16 sample ($n = 78$) performed above the 10th percentile in all three composites at all ages. In total, 104
17
18 families (72.7%, at risk $n = 44$, no risk $n = 60$) returned the questionnaire. The mean age of the children
19
20 at the time of the completion of the questionnaire was 25.3 months ($SD = 1.2$, range 24-30 months). The
21
22 ITC composite scores at 12, 15, and 18 months were compared between the children who had data at
23
24 age 2 ($n = 99$, 101, and 98 respectively) and those who did not, ($n = 223$, 204, and 181). Effect sizes
25
26 were calculated using partial eta squared (η_p^2). Significant differences between the children emerged in
27
28 the speech composite at 15 months, $F(1, 302) = 17.557$, $\eta_p^2 = .055$, $p = .000$ after controlling for
29
30 multiple comparisons (Table SM1).
31
32
33
34
35
36

37 At age 3, the same subset of families was invited for individual assessments of vocabulary. Of
38
39 these families, 112 (at-risk $n = 56$, no risk $n = 56$) agreed to participate. The mean age of the children at
40
41 the time of the assessment was 36.7 months ($SD = 0.8$, range 36-41). When comparing the children with
42
43 data at age 3 ($n = 109$, 108, and 105 at 12, 15, and 18 months of age respectively) and those without ($n =$
44
45 213, 196, and 174), small but significant differences in the social composite at 15 months, $F(1, 303) =$
46
47 12.282, $\eta_p^2 = .039$, $p = .001$, and speech composite at 15 months, $F(1, 302) = 15.346$, $\eta_p^2 = .048$, $p = .000$
48
49 and 18 months, $F(1, 277) = 12.948$, $\eta_p^2 = .045$, $p = .001$ of age remained after controlling for multiple
50
51 comparisons (Table SM1). In both 2 and 3 year data comparisons, the significant differences resulted
52
53 from the participating children having lower mean and showing larger variation than the children
54
55 without follow-up data. In the present study all the available data from the assessments at ages 2 and 3
56
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

years were used.

When the children were aged 4 years 7 months all the originally participating families were sent a questionnaire concerning their child's language and communication skills. Of the 508 families, 473 (93.1%) were reached, and 296 (62.6% of reached; 58.3% of the original sample; total attrition rate 41.7%) returned the questionnaire. The mean age of the children at the time of the completion of the questionnaire was 56.9 months ($SD = 4.0$, range 52-69). There were no significant differences in ITC scores at ages 12, 15, and 18 months between the children who participated in this follow-up and those who did not. In the present study, children who had early data only from ages 21 and 24 months were excluded, and thus data from 253 children were used.

At age 5 years 3 months (5;3), a subsample of 102 children were invited for individual follow-up assessment. Primarily, children with full datasets from the previous assessment points (early questionnaire data, vocabulary data from either age 2 or 3 or both, and questionnaire data from age 4;7, $n = 70$) were selected to ensure adequate data for studying development over time. The sample was supplemented with children whose parents reported concerns related to language and communication, hyperactivity, or executive functions in the previous follow-up stage at age 4;7 ($n = 32$). The mean age of the children at the time of the assessment was 62.3 months ($SD = 0.5$, range 61-65 months). No significant differences were observed in the ITC scores at ages 12, 15, and 18 months between the children who participated in this follow-up ($n = 93, 97$, and 88 , respectively) and those who did not ($n = 229, 208$, and 191). In the present study, all the available data were used.

The final follow-up was conducted during the spring term of the first grade (mean age = 93.3, $SD = 3.9$, range 86-103 months). All the originally participating families were sent a questionnaire on their child's language and communication skills. Altogether, 453 families (89.2%) were reached and 273 (60.3 % of reached; 53.7 % of the original sample; total attrition rate 46.3%) returned the questionnaire. There were no significant differences in ITC scores at ages 12, 15, and 18 months between the children who participated in this follow-up and those who did not. In the present study,

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 children with early data only from ages 21 and 24 months were excluded, resulting in a sample of 236
3
4 children.
5

6 7 **Measures**

8
9 Parents completed questionnaires every three months between the ages 6 to 18 months and at the
10
11 follow-ups at ages 2 years, 4;7, and first grade. Face-to-face assessments were administered at the ages
12
13 of 3 years, and 5;3 (see Table 1.).

21
22

23 **Early development measure.** The Finnish version of the Infant-Toddler Checklist (ITC) of the
24
25 Communication and Symbolic Behavior Scales Developmental Profile (CSBS DP, Laakso, Poikkeus, &
26
27 Eklund, 2011; Wetherby & Prizant, 2002) was used to obtain parental estimates of their children's early
28
29 communication skills. The ITC is one of the most comprehensive parent-report screening tools for
30
31 prelinguistic and early language skills currently available (for a review of methods, see Crais, 2011).
32
33 The questionnaire covers three composites of development that address several relevant aspects of
34
35 prelinguistic communication, such as emotion and eye gaze, gestures, and communication (social),
36
37 sounds and words (speech), and understanding and object use (symbolic). Wetherby and Prizant (2002)
38
39 report Cronbach's alphas (α s) ranging from .87 to .99 for the three composites combined over the age
40
41 span of 6 to 24 months, which indicates a high degree of internal consistency. In the present data, the
42
43 Cronbach's α s over the age span of 6 to 18 months ranged from .80 to .89, and by age (6, 9, 12, 15, and
44
45 18 months; $ns = 191-320$) from .68 to .73 for the social composite, from .47 to .63 for the speech
46
47 composite, and from .38 to .58 for the symbolic composite.
48
49
50
51
52

53
54 The ITC has been shown to be able to detect developmental growth and produce relatively stable
55
56 rankings of children over short periods of time (Reilly et al., 2006; Wetherby et al., 2002), although
57
58 indications of instability in ITC rankings both between and within individuals have also been reported
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

(Darrach et al., 2003). Longitudinal connections between ITC scores and receptive and expressive language at 2 and 3 years of age (Wetherby, Goldstein, Cleary, Allen, Kublin, 2003), and between the ITC and later communication difficulties, including autism spectrum disorders (Wetherby et al, 2008) have been reported. However, studies extending the follow-up period beyond the toddler years remain scarce (for exceptions, see Määttä et al., 2012, 2014; Reilly et al., 2006).

Follow-up measures

Measures at 2 years (n = 104). The vocabulary scale, sum of noun and verb inflections, and maximum sentence length subscales of the Finnish version of the MacArthur-Bates Communicative Development Inventories Words and Sentences (MBCDI; Fenson et al., 1994; Lyytinen, 1999) was used as a measure of early expressive vocabulary. Cronbach's α for the vocabulary scale was .95.

Measures at 3 years (n = 112). Children's receptive vocabulary was assessed with the Peabody Picture Vocabulary Test (PPVT; Dunn & Dunn, 1981) and expressive vocabulary with Boston naming (Kaplan, Goodglass, & Weintraub, 1983). Cronbach's α s were .94 for PPVT and .82 for Boston naming.

Measures at 4;7 (n = 253). Children's language-related difficulties were assessed using the questionnaire Five to Fifteen (FTF; Kadesjö et al., 2004). As the FTF is a symptom questionnaire based on parent report the results are regarded to represent parental concerns as opposed to clinically evaluated difficulties. The language domain of the FTF includes three subscales that cover comprehension, expressive, and communication skills. The Cronbach's α s for the scales were .66 for comprehension, .87 for expressive and .71 for comprehension.

Measures at 5;3 (n = 98-102). The language tasks were selected to measure a range of language-based skills that tap different dimensions of language in both the receptive and expressive domains. The Similarities subtest (SI, WPPSI-R; Wechsler, 1995) was used to assess verbal abstract reasoning and conceptualization abilities. Single-word receptive vocabulary was assessed with a short version of Peabody Picture Vocabulary Test – Revised (PPVT; Dunn & Dunn, 1981). As a measure of receptive grammar, we used the Korpilahti Auditory Sentence Comprehension test (SC; Korpilahti, 1996), which

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

assesses the ability to process semantic and syntactic information in sentences of increasing complexity. The Verbal Fluency subtest of NEPSY-II (VF; Korkman, Kirk, & Kemp, 2008) was used to assess verbal fluency and vocabulary through the ability to generate words within specific semantic categories.

The memory tasks were selected to measure different subsystems of Baddeley's (2003) model of working memory. The phonological loop (i.e., auditory short-term memory) was assessed with the Digit Span- forwards subtest (DSf, WISC-III; Wechsler, 1999) and the Repetition of Nonsense Words task (NWR, NEPSY; Korkman, Kirk, & Kemp, 1997). The Digit Span- backwards subtest (DSf, WISC-III; Wechsler, 1999) was used to assess the central executive and the Sentence Repetition task (SR, NEPSY-II; Korkman et al., 2008) to assess the episodic buffer.

Measures in first grade (mean age 7;9, range 7;2-8;4, n = 236). The Finnish version of the Children's Communication Checklist-II (CCC-2; Bishop, 2003; 2014) was used to assess children's language and communication difficulties. The questionnaire includes four subscales evaluating language-related abilities (speech, syntax, semantics, coherence; Cronbach's $\alpha = .91$) and four subscales concentrating on pragmatics (inappropriate initiations, stereotyped language, use of context, nonverbal communication; $\alpha = .92$).

Data analyses

The repeated measures of early communication skills (the three composites of the ITC: social, speech, and symbolic) were analyzed using a type of second-order multivariate Latent Growth Curve modeling (LGC, Bollen & Curran, 2006; factor-of-curves, Duncan, Duncan, & Strycker, 2006). The analyses were performed using the Mplus statistical package (version 7; Muthén & Muthén, 1998-2010). The missing data function in Mplus enables all the observations in the data to be used in estimating the parameters of the models. Because some of the variables were skewed, the robust MLR estimation method was used (Muthén & Muthén, 1998-2010). The goodness-of-fit of the estimated LGC models was evaluated using the χ^2 test ($p > .05$), the Comparative Fit Index ($CFI \geq .95$), the Tucker-Lewin Index ($TLI \geq .95$), the Root Mean Square Error of Approximation ($RMSEA < .06$), and

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

Standardized Root Mean Square Error of Approximation (SRMR < .08) (Hu & Bentler, 1999; Muthén & Muthén, 1998-2010). Instead of as definitive cut-off criteria, the values of the fit indices were used as guidelines for evaluating the model fit (for a critical discussion, see Marsh, Hau, & Wen, 2004). Greater weight was given to the other fit indices than to chi-square, as the chi-square value is known to be sensitive to large sample sizes (Miles & Shevlin, 2007). The model modification indices, alongside with theoretical considerations, were utilized in specifying the model.

In the analysis, the growth curves were first applied simultaneously to each ITC composite, estimating the initial level of each composite (i.e., the level), the average rate of growth (i.e., the slope), and individual variation in the initial level and growth. These first-order factors described individual differences within each ITC composite. Second-order common factors (common level and common growth) were then added to describe commonality (i.e., to model the correlation structure) among the first-order factors. The associations of early communication development (the early LGC model) with later language ability were explored by regressing the follow-up measures on the common level and growth factors. Skill- and age-specific connections were tested by building the specific pathways suggested by the model modification indices. The regressions were run separately for each follow-up stage. Raw scores were used in all the analyses.

Results

A latent growth curve (LGC) model for early communication development

The means and standard deviations of the three ITC composites (social, speech, symbolic) between ages 6 and 18 months are shown in the upper part of Table 2. All three composites showed marked growth throughout the assessment period and all the successive measurements within the composites correlated significantly with each other (social $r = .47 - .72$, $p < .001$; speech $r = .34 - .79$, $p < .001$, and symbolic $r = .40 - .68$, $p < .001$; for a full correlation matrix, see Table SM3) with a large effect size (Cohen, 1992). However, there were also notable differences between individuals throughout the period. That is, overlap in the scores was observed between the different age stages – the highest performing children at

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

only 6 months of age scored almost as high as the lowest performing children at ages 15 and 18 months (95 % confidence intervals).

Insert Table 2 about here.

A LGC model for each of the three early communication composites was estimated simultaneously (see Figure 2). Altogether, 427 children were included in the analysis. The coverage of the elements in the covariance matrix varied from 31.6 to 75.4 % (see Table SM4). Due to the sequential nature of the data, all the successive measurements were allowed to correlate with each other within the composites. Following the suggestions of the modification indices and visual inspection of the individual growth curves, nonlinear growth was estimated: the first and last factor loadings on the growth factors of each communication composite were fixed, and the factor loadings at ages 9, 12, and 15 months were estimated freely. The level and growth factors of the three composites were allowed to correlate, and the correlations were high and significant both between the level factors ($r = .57-.81, p < .001$), and the growth factors ($r = .48 - .67; p < .001 - .010$).

A second-order factor structure was then added to the previous model in order to model the correlation structure between the first-order factors. The three first-order level factors were set to load onto the second-order level factor (common level) and the three first-order growth factors were set to load onto the second-order growth factor (common slope; see Figure 2). Because of high correlations between the residuals of the different composites at ages 9, 12 and 15 months, specific factors by age were added to explain the residual covariance. The loadings of the three composites were set equal across the three measurements. The model fitted the data well: $\chi^2(73) = 87.405, p = .120, CFI = .991, TLI = .987, RMSEA = .021$ and $SRMR = .083$.

58
59
60

All loadings on the second-order level and growth factors were significant and positive, with small differences in the magnitude of the loadings between the different composites. The second-order level factor explained (R^2) 74 % of the variance in the first-order level factor of the social composite, 72 % of that of the speech composite, and all of the variance in the level of the symbolic composite (due to a small negative residual variance, the residue of the first-order level factor of the symbolic composite was set to zero). The second-order growth factor explained 88 % of the variance in the first-order growth factor of the social composite, and 91 % of the symbolic composite. For the speech composite, the percentage explained was somewhat smaller (66 %), although significant. The second-order level and growth factors correlated negatively ($r = -.48$), indicating that the rate of growth was steeper for children who started at a lower initial level. The residuals of the first-order level factors of the social and speech composites, and the first-order growth factor of the speech composite were significant (.26 - .34, $p = .010-.031$). This indicates that, despite good model fit, there was skill-specific variation that was not explained by the common level and growth factors. In addition, the presence of the age-specific factors at ages 9, 12 and 15 months suggest that there is also age-specific variation, not captured by the growth model.

In sum, the LGC model of early communication skills suggested that there is a large amount of shared variance in the development of early social, speech, and symbolic skills. That is, individuals tend to be on a similar level (i.e. to have similar ranking relative to others) across the different skills, and the rate of development tends also to be similar across the skills, especially in social and symbolic composites. However, despite the notable commonalities, there is also significant skill- and age-specific variation, as indicated by the significant residual variances of the skill-specific factors, and the emergence of the age-specific factors.

Early communication development and later language and communication skills

The longitudinal associations of the LGC model for early communication development with later

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 language and communication development were explored separately for each follow-up measurement at
3
4 ages 2, 3, 4;7, and 5;3 years, and in first grade. The analysis was performed in two steps. First, the
5
6 follow-up measures were regressed on the second-order factors (i.e., common level and growth).
7
8
9 Second, in order to explore possible skill- and age-specific pathways, the specific associations suggested
10
11 by the model modification indices were tested. For a summary of the model fit indices see Table SM5 in
12
13 the online Supporting Material. The regression coefficients together with the tested specific associations
14
15 are summarized in Table 3.
16
17

19 -----
20
21 Insert Table 3 about here.
22
23 -----
24

25
26 **LGC and vocabulary at 2 years (n = 104).** The MBCDI vocabulary, inflections and maximum
27
28 sentence length (MSL) were used as the outcome measures. These data were available for 24 % of the
29
30 children in the early LGC model. The resulting model fitted the data well: $\chi^2(112) = 153.548, p = .0056,$
31
32 $CFI = .979, TLI = .971, RMSEA = .029, SRMR = .091.$ The level and growth of early communication
33
34 skills explained 32.4 % ($\beta_L = .32, \beta_G = .64$) of the variance in the MBCDI vocabulary, and the growth of
35
36 early communication skills alone explained 41.1 % ($\beta_G = .69$) and 46.7 % ($\beta_G = .74$) of the variances of
37
38 the MBCDI inflections and MSL, respectively.
39
40
41

42
43 **LGC and vocabulary at 3 years (n = 112).** At three years of age, the Boston naming, and
44
45 PPVT were administered to a subsample of the children (26 % of the children in the LGC model). The
46
47 model fitted the data well: $\chi^2(99) = 119.435, p = .0793, CFI = .988, TLI = .984, RMSEA = .022,$ and
48
49 $SRMR = .083.$ For Boston naming, the common growth in early communication skills explained 27.6 %
50
51 ($\beta_G = .58$) of the variance. For the PPVT, both the common level and growth of early communication
52
53 skills together explained 10.5 % ($\beta_L = .29, \beta_G = .33$) of the variance.
54
55

56
57 **LGC and parental concerns of language development at age 4;7 (n = 253).** Parents reported
58
59 language related difficulties in the areas of expressive and receptive language and communication skills
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 using the FTF when the children were aged 4;7. These data were available for 59 % of the children in
3
4 the LGC model. The model fitted the data well: $\chi^2(112) = 136.459, p = .0579, CFI = .987, TLI = .982,$
5
6 $RMSEA = .022,$ and $SRMR = .078.$ Together, the common level and growth of early communication
7
8 skills explained 15.0 % ($\beta_L = -.28, \beta_G = -.43$), 19.8 % ($\beta_L = -.26, \beta_G = -.50$), and 20.9 % ($\beta_L = -.32, \beta_G = -.51$)
9
10 of the variances of the parent-reported concerns in the areas of receptive and expressive language, and
11
12 communication, respectively.
13
14

15
16 **LGC and language and verbal working memory skills at 5;3 (n = 102).** Two factors were
17
18 constructed from the tasks administered at the age of 5;3 months to a subsample of the children (24 % of
19
20 the children in the LGC model). The language factor included the Similarities, PPVT, Verbal Fluency,
21
22 and Sentence Comprehension tasks. The memory factor included the Digit Span forwards and
23
24 backwards, Nonword Repetition, and Sentence Repetition tasks. The two parts of the Digit Span task
25
26 were allowed to correlate. The resulting model fitted the data well: $\chi^2(207) = 258.160, p = .0090, CFI$
27
28 $= .973, TLI = .967, RMSEA = .024,$ and $SRMR = .089.$ The common growth factor of early
29
30 communication skills explained 33.4 % ($\beta_G = .65$) of the variance in the language factor, and 53.3 % (β_G
31
32 $= .74$) of the variance in the memory factor. The at-risk status was added to the model as a covariate in
33
34 order to control for the possible effects it may have on the follow-up outcome. However, the
35
36 connections were not significant (language $\beta = .02, p = .85$; memory $\beta = -.09, p = .29$).
37
38
39
40
41

42 **LGC and communication skills in the first grade (n = 236).** Parents reported strengths and
43
44 difficulties in language and communication using the Children's Communication Checklist-II when
45
46 their children were in the first grade. These data were available for 55 % of the children in the LGC
47
48 model. Two factors were constructed from the CCC-II subscales based on their content. The language
49
50 factor included the subscales Speech, Syntax, Semantics, and Coherence. The communication factor
51
52 included the subscales Inappropriate initiation, Stereotyped language, Use of context, and Non-verbal
53
54 communication. Correlations were allowed within the factors for Speech and Syntax, and Stereotyped
55
56 language and Non-verbal communication. The correlation between the factors was .87 ($p < .000$). The
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT
resulting model fitted the data well: $\chi^2(206) = 236.476, p = .0714, CFI = .991, TLI = .988, RMSEA = .018$, and $SRMR = .071$. The common level and growth factors explained 48.2 % ($\beta_L = -.31, \beta_G = -.78$) and 38.9 % ($\beta_L = -.24, \beta_G = -.70$) of the variances in the language and communication factors.

Skill- and age-specific pathways. All in all, there were 108 possible specific pathways (12 outcome measures x 9 specific factors), and thus the significance level was set at $p < .001$. Of these possible pathways, 17 were tested based on the model modification indices (see Table 3 and online Supporting Material). None of these pathways were significant at the .001 significance level, while three of these pathways approached significance: the growth factor of the speech composite to the memory factor at age 4;7 ($p = .002$) and to the language factor in first grade ($p = .007$), and the age-specific factor at 15 months of age to language in first grade ($p = .007$).

Summary of the common and specific connections. The initial level and, in particular, the growth of early communication skills were significant predictors of later language ability. The children who had a higher initial level of communication skills showed better productive vocabulary at 2 years and better receptive vocabulary at 3 years, and their parents reported fewer language- and communication-related concerns at age 4;7 and in first grade. Children who had a faster rate of growth in early communication skills during the period from 6 to 18 months showed better vocabulary skills at ages 2 and 3 years, had fewer parent reported concerns about language and communication development at 4;7 and in first grade, and showed better language and verbal working memory skills at age 5;3. The percentage explained by the level and growth factors varied from 10.5 to 53.3 %. The model modification indices suggested several skill- and age-specific pathways, but none of these pathways were significant at the .001 significance level, and thus, no specific paths were added to the regression models.

Discussion

The aim of this study was to explore the co-development of several early communication skills during the prelinguistic period, and the associations between this development and later language ability. Early

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 communication skills showed fast growth throughout the ages from 6 to 18 months. There were large
3
4 individual differences in the development of these skills and these differences showed rather high
5
6 stability throughout the prelinguistic period. The development in different early communication skills
7
8 showed a large amount of shared variance which was indicated by the significant and high loadings on
9
10 the common level and growth factors. However, despite the notable commonalities in development
11
12 across skills, significant skill- and age-specific variance was also present. The follow-ups were
13
14 conducted at several time points using multiple measures and sources. The level and especially the
15
16 growth of early communication skills were significant predictors of later language ability, explaining
17
18 between 10.5 to 53.3% of the outcome variances. No reliable skill- or age-specific connections were
19
20 found. The results support a continuum from prelinguistic to linguistic ability (Bruner, 1983), and the
21
22 dimensional view of language ability (Rescorla, 2009, 2013), by indicating that the individual variations
23
24 in early language endowment show consistency that extends far beyond the toddler years.
25
26
27
28
29

30 **The development of early communication skills between 6 and 18 months of age**

31
32
33 Marked growth was evident in all three areas of early communication development (social,
34
35 speech, and symbolic) across the age span from 6 to 18 months. Also evident was large interindividual
36
37 variation in the development of these early skills, as shown by the overlap in scores across the different
38
39 ages. However, despite the change in the mean scores at group level and large interindividual variation,
40
41 both continuity and stability were present. The high correlations between the successive measurements
42
43 suggested continuity in individual differences in these skills over age, whereas the significant loadings
44
45 of the measurements at each age on the skill-specific level and growth factors indicated stability. That
46
47 is, within a composite, the relative standings of individuals in their development were rather consistent
48
49 over time.
50
51
52

53
54 As expected, the LGC model suggested a large amount of shared variance in the development of
55
56 early social, speech, and symbolic skills. The level factors of the three composites loaded significantly
57
58 on the common level factor, indicating that individuals tended to have a similar ranking relative to
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 others across the three composites. In other words, individuals performing high in one composite were
3
4 also likely to perform high in the other two. Likewise, the three growth factors of the three composites
5
6 loaded significantly on the common growth factor, indicating that the relative pace of development was
7
8 similar across the composites. For example, individuals who showed slow development in one skill
9
10 composite tended to be slow in the other two as well. Development in the social and symbolic
11
12 composites, in particular, seemed to go side by side.
13
14
15

16 Thus, when multiple early communication skills were assessed repeatedly with a parental
17
18 screener, early communication ability emerged as a rather continuous and stable characteristic of
19
20 individual differences during the prelinguistic period, that is, the first two years of life. This is in line
21
22 with previous results on early communication skills obtained by observational methods (Watt et al.,
23
24 2006). However, the common level and growth factors did not explain all of the variation in
25
26 development, as shown by the significant residual variances of the skill-specific factors and the
27
28 emergence of age-specific factors. This indicates that notable skill- and age-specific variation was also
29
30 present in early communication development, an issue we will turn to later on.
31
32
33
34

35 **The development of prelinguistic communication skills and later language ability**

36
37 Both common level and growth of early communication were significant predictors of later
38
39 language and communication ability. Together, the common level and growth factors explained 10.5 to
40
41 53.3 % of the variance in the follow-up measures. These percentages are comparable to those obtained
42
43 by Wetherby et al. (2002; 2003), who found that the ITC, filled in between 12 and 24 months, explained
44
45 20-51 % of the variances in receptive and expressive language outcomes at 2 and 3 years of age. Our
46
47 results consolidate and expand these results by suggesting that the predictive relation between early
48
49 communication skills and later language ability is present as early as at 6 months of age, and holds
50
51 longitudinally up until 8 years of age.
52
53
54
55

56 The connection was stronger for the common growth factor, which was significantly connected
57
58 to all of the follow-up language and communication measures from age 2 years to first grade. A faster
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 rate of growth in early communication skills consistently led to better language ability and fewer parent-
3
4 reported difficulties later on. Our results support the suggestion that the pace of development, rather
5
6 than the level at any given age, better reflects the language acquisition potential of the child, and thus
7
8 might predict later language development more accurately (Rowe et al., 2012). A slow pace of
9
10 development might be an indicator of risk for later language difficulties and could be useful in
11
12 identifying which children might go on to have persistent language difficulties (Lyytinen et al., 2006;
13
14 Rescorla et al., 2000).

15
16
17
18
19 The amount of variance explained by the early communication model did not decrease over time,
20
21 nor was it consistently the largest when the same source of information was used (parental reports). In
22
23 addition, it did not seem to be dependent on whether the follow-up sample was based on a selected
24
25 subsample (ages 2, 3, and 5;3) or the full sample (ages 4;7 and first grade). Thus, our results cannot be
26
27 accounted for solely by the temporal closeness of the assessments, shared source variance, or sampling
28
29 procedures. Interestingly, the strongest predictive relation was found between the growth of early skills
30
31 and later verbal working memory capacity. Although based on a selected subsample of children at age
32
33 5;3, we do not believe this finding results from sampling issues, since there were no significant
34
35 differences in early communication skills (the ITC) between the children who participated in the follow-
36
37 up at 5;3 and those who did not, and since the at-risk status was not a significant covariate. Instead of
38
39 being an isolated cognitive skill, language has been shown to be rather inextricably linked to a set of
40
41 processes shared with other realms of cognition early in life (including memory, attention, and
42
43 processing speed; e.g., Rose, Feldman, & Jankowski, 2009). Memory processes are considered to be an
44
45 important underlying component of language development (Gathercole, 2006; Heimann et al., 2006),
46
47 and have been shown to yield a significant level of consistency over time (Rescorla, 2013). Our results
48
49 seem to fit in with these findings. Thus, the development and application of infant measures that can tap
50
51 early memory skills more specifically than the ITC in order to provide more information about the co-
52
53 development of early language and memory, might prove worthwhile in trying to predict language
54
55
56
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

outcome.

Skill- and age-specific factors and later language ability

The common level and growth factors captured the variance shared by the three composites across age. However, as indicated by the significant residual variances of the skill-specific factors and the emergence of age-specific factors at 9, 12 and 15 months of age, significant skill- and age-specific variation was also apparent in early communication development. The contribution of these factors to later language development was examined by testing the specific pathways suggested by the model modification indices. Several such pathways were tested, but, contrary to our expectations, none of them reached significance. These results seem to be in line with those of previous studies reporting that when other aspects of communicative development are controlled for, the unique contributions of specific skills diminish (Lyytinen et al., 2001; Salley et al., 2013) and that the amount of shared variance is notably large relative to the unique contributions (Watt et al., 2006; Wetherby et al., 2002). However, despite the large body of research on prelinguistic predictors of language development, studies that have considered multiple concurrent predictors and their unique contributions to later development remain scarce and the results are not able to lead to firm conclusions. While the tested pathways failed to reach significance in the present study, they nonetheless raise interesting topics for future research.

There are several possible reasons we did not find any reliable specific associations. As indicated by the significant correlations found between early socio-cognitive skills in earlier studies (Laakso et al., 1999; Watt et al., 2006; Wetherby et al., 2002), these skills are highly interrelated, and thus specific connections might be difficult to discern. It is possible that a broadband screener is only able to describe the common trends in development, and that to be able to capture the more specific processes of development, a more fine-tuned measurement is needed. For example, Laakso et al. (1999) found that parental ratings of intentional communication yielded general associations to later language ability, whereas the associations from observed joint attention to later language varied depending on the specific aspects of the joint attention behaviors under observation. Watt et al. (2006) also found, using

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 observational methods, that some skills make a unique contribution to language outcome despite sharing
3
4 a substantial amount of variance. In addition, Brooks and Meltzoff (2008) found that observed pointing
5
6 in an experimental setting, but not parental report of pointing, was a significant predictor of vocabulary
7
8 growth. Specific predictive relations might also be stronger when the focus of assessment is centered
9
10 more on domain-general skills, such as attention (Salley et al., 2013) and memory (Heimann et al.,
11
12 2006; Rose et al., 2009), which have been shown to show discreteness already early on in life (Rose,
13
14 Feldman, & Jankowski, 2005).
15
16

17 18 **Strengths, limitations and further directions** 19

20
21 This study examined the continuity and stability of language and communication development
22
23 from 6 months to first grade. So far, few studies have examined developmental continuity and predictive
24
25 relations starting from such an early age and extending over a notably long follow-up period (however,
26
27 see Reilly et al., 2006). The use of a rather large community-based sample, repeated assessment of early
28
29 communication skills during the prelinguistic period, the inclusion of social and symbolic abilities in
30
31 addition to oral communication in the early assessments, and a diverse assessment of language and
32
33 communication with the inclusion of working memory measures in the follow-ups are clear assets of the
34
35 study.
36
37
38

39
40 Although the present study established that strong longitudinal associations exist between
41
42 prelinguistic development and later language ability, several important limitations must be noted. First,
43
44 despite its initial size, our study is limited by the nature of the sample. Due to sampling decisions and
45
46 attrition, the number of children having data at each follow-up ranged between 23 – 26% in selected
47
48 subsamples, and between 60 - 63% in population follow-up samples. The variation in the subsample
49
50 sizes and measures makes comparison of the coefficients of determination (R^2) challenging. However,
51
52 these values did not systematically vary according to the coverage of the initial sample or the source of
53
54 information (parent report or psychometric assessment). It is also important to bear in mind that in some
55
56 of the follow-up samples (2;0, 3;0, and 5;3) children with possible risks for language difficulties were
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 slightly oversampled and thus, inferences based on these follow-ups should be interpreted with caution.
3
4 However, although there were some differences in the ITC composite scores between the children
5
6 participating and not participating in these follow-ups, these differences did not seem to be systematic
7
8 across the follow-ups.
9

10
11 Second, our parental questionnaire on early communication skills was comprehensive in its
12
13 contents, but nevertheless short and designed for screening purposes. Parent-report measures of
14
15 communication and language skills have been shown to be reliable and valid, and to correlate with
16
17 concurrent and subsequent behavioral measures (e.g., Feldman et al., 2005; Laakso et al., 1999).
18
19 However, more direct assessments of the possible (socio)-cognitive precursors of language, such as
20
21 working memory and processing efficiency (e.g., Fernald & Marchman, 2012), attentional capacity
22
23 (Rose et al., 2009), joint attention and gestures (Beuker et al., 2013), and symbolic play (Bruce et al.,
24
25 2003) in infancy, would aid in better understanding the processes that underlie the emergence and
26
27 further development of language. Our results suggest that the role of early working memory especially
28
29 should be studied further. From a clinical perspective, however, studying feasible and implementable
30
31 methods is essential.
32
33
34
35
36

37
38 Third, we did not control for possible confounding variables related to the child (e.g., gender,
39
40 nonverbal ability) or the family (e.g., parental age and education) that could affect the estimation of
41
42 stability (see, Bornstein et al., 2013; McKean et al, 2015). It has been shown that these variables show
43
44 little explanatory power in the early stages of development (5-6% in Reilly et al., 2006). At later ages,
45
46 they have been shown to contribute more to later language status (19-21% in Reilly et al., 2010), but to
47
48 show only modest discrimination between children with and without low language ability. For the
49
50 current study, data related to birth and family are, however, reported in the Supporting material along
51
52 with descriptions of Finnish society. Fourth, it is likely that there are other important risk or resilience
53
54 factors that contribute to later language ability that we did not assess in this study. As language develops
55
56 in social interaction, factors related to the social environment might prove useful (Bruner, 1983; Paavola
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2 et al., 2006). For example, maternal responsivity has been shown to mediate the relation between early
3
4 communication and later language (Yoder & Warren, 1999). In addition, it is likely that the use of
5
6 speech and language therapy services affect children's outcomes (Law, Garrett, Nye, 2003).
7

8
9 Unfortunately, we did not have this information for the whole sample, and thus could not control for it.
10

11
12 Finally, it is important to bear in mind that the results obtained in this study reflect predictive
13
14 relations at the group level. Studying stability and prediction at the individual level was not within the
15
16 scope of this study. However, examination of the persistency of at-risk status and estimations of
17
18 sensitivity, specificity and other predictive values is a natural next step in our research. The sensitivity
19
20 and specificity estimates obtained in previous studies using the ITC have been relatively good (81-89 %
21
22 and 70-79 %) up to three years of age (Wetherby et al., 2003).
23
24

25
26 The present study contributes to the literature on early language development by adducing
27
28 further evidence for the link between prelinguistic communication and later language ability. The results
29
30 support the dimensional view of language ability (Rescorla, 2009, 2013) by showing that instead of a
31
32 specific skill, the combined development of several early communication skills (i.e., the early language
33
34 endowment) is more predictive of later language ability. Our results conform to the views of Bates
35
36 (2004) and Rescorla (2009, 2013) that language ability builds up from the interactions of several
37
38 interrelated early communication skills that do not map one-on-one to later abilities. Our results also
39
40 advocate developmental surveillance of early communication skills by showing that the pace of
41
42 development, rather than the level at any given age, is more predictive of later development. In addition
43
44 to providing a better understanding of developmental processes in typical development, these results
45
46 have important implications for early screening procedures. By assessing multiple early communication
47
48 skills concurrently, and by following the development in these skills over short periods of time, we
49
50 might be able to identify at-risk children more accurately and at an earlier age.

5
6
7

Age	n	Source	Measure	Components	Scoring
6, 9, 12, 15, 18, 21, and 24 months	203-322	Parent report	Communication and Symbolic Behavior Scales – Infant Toddler Checklist (ITC)	Social	Sum of 13 ordinal items on the ITC measure (max. 26)
				Speech	Sum of five ordinal items on the ITC measure (max. 14)
				Symbolic	Sum of six ordinal items on the ITC measure (max. 17)
14 years	104	Parent report	MacArthur-Bates Communicative Development Inventories – Words and Sentences Inventory	Vocabulary	Number of words from a pre-specified list of 595 that the child says
				Inflections	Sum of noun and verb inflections the child uses (max. 16)
				Maximum sentence length	Average morpheme length of three sentences
19 years	112	Individual assessment	Boston naming	Expressive vocabulary	Sum of 60 binary items
			Peabody Picture Vocabulary Test	Receptive vocabulary	Sum of 166 binary items
24;7	253	Parent report	Five to Fifteen (FTF) – Language subscales	Comprehension	Mean of five ordinal items on the FTF measure
				Expressive	Mean of 13 ordinal items on the FTF measure
				Communication	Mean of three ordinal items on the FTF measure
25;3	98-102	Individual assessment	WPPSI-R – Similarities	Verbal reasoning	Sum of 12 binary and eight ordinal items (max. 28)
			Peabody Picture Vocabulary Test-Revised	Receptive vocabulary	Sum of 30 binary items
			Korpilahti Auditory Sentence Comprehension Test	Receptive grammar	Sum of 30 binary items
			NEPSY-II – Verbal Fluency	Verbal productivity	Sum of semantically correct words produced in 60 seconds
			WISC-III – Digit Span	Working memory	Sum of 12 (forward) and 10 (backward) binary items
			NEPSY – Repetition of Nonsense Words	Working memory	Sum of 16 binary items
34 st grade	236	Parent report	Children’s Communication Checklist - II	Language: Speech, Syntax, Semantics, Coherence	Four subscales, sum of seven ordinal items (5 addressing deficits, 2 strengths) in each scale (max. 112)
				Communication: Inappropriate initiation, Stereotyped language, Use of context, Non-verbal communication	Four subscales, sum of seven ordinal items (5 addressing deficits, 2 strengths) in each scale (max. 112)

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

Continuity from prelinguistic communication to later language ability: a follow-up study from infancy
to school age

Appendix S1

Method

Participants and procedure

The original sample of 508 children was recruited through community-based child health care clinics in the city of Jyväskylä, Central Finland. Child health care clinics provide free services for all families with children between ages 0 to 6. The services are focused on health promotion, risk assessment, and disease prevention. Visits are made to the clinic 10 to 15 times during the first two years of life, and thereafter annually or at 18 month intervals. The clinics are regularly attended by over 95 % of Finnish parents and their children (for a more detailed description of pre- and postnatal care for families, see Callister, Lauri, & Vehviläinen-Julkunen, 2000). All the clinics in the area (population base close to 100,000, and age cohort of about 900 at the time) volunteered to participate in the study. The Infant-Toddler Checklist (ITC, part of the Communication and Symbolic Behavior Scales – Developmental Profile, Wetherby & Prizant, 2002) was introduced to the families by the nurses at the clinics. Children were eligible for participation if aged between 6 and 24 months at time of recruitment.

After giving their consent and completing the first ITC questionnaire, parents were asked to fill in a new questionnaire every three months until the child was 24 months of age (i.e., a maximum of seven times; at ages 6, 9, 12, 15, 18, 21, and 24 months). The sample sizes for the measurement points were $n = 229$ at 6 months, $n = 203$ at 9 months, $n = 322$ at 12 months, $n = 305$ at 15 months, $n = 279$ at 18 months, $n = 273$ at 21 months, and $n = 330$ at 24 months of age. For the majority of the sample (67.9%), data were available from at least three measurement points. The total number of

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 forms filled in by parents depended on their child's age at the time of completing the first
4
5 questionnaire and on how many of the subsequent questionnaires they completed. In the present study,
6
7 the data from the measurements conducted between 6 and 18 months were used, yielding a total
8
9 sample of 427 children.
10
11

12
13 After the early questionnaire data collection phase, subgroups of the original 508 participants
14
15 were followed at ages 2 and 3 years (parent report and individual assessments), 4;7 (parent report),
16
17 and 5;3 (individual assessment), and in the spring term of the first grade (age range 7;5 – 8;4, parent
18
19 report). During the follow-ups at 2, 3, and 5;3, only a small subset of families were contacted due to
20
21 time and resource limitations. Thus, the subgroups were constructed to include a sufficient number of
22
23 children showing possible risks for language and communication development. This form of data
24
25 collection enables also comparison of at-risk and typically developing children. At ages 4;7 and first
26
27 grade, all the originally participating families were contacted. The group differences in the early ITC
28
29 scores are summarized in table SM1. .
30
31
32
33

34
35 Demographic information by subsamples is presented in Table SM2. The Finnish population
36
37 of 5.4 million is relatively homogeneous in ethnicity, culture, religion, and language. All the
38
39 participating children were Caucasian and spoke Finnish as their native language. Data related to birth
40
41 and family were collected at the initial recruitment stage (data available for 472 - 485 children).
42
43 Fourteen children (2.9 %) had been born preterm (i.e., gestational age less than 36 weeks). Sample
44
45 mean birth weight was 3.5 kg ($SD = 0.6$, range 1.1 -5.4). Slightly over half ($n = 267$, 56.6 %) the
46
47 children were firstborns. At time of recruitment, 19 (3.9 %) families reported single parenthood. This
48
49 is a markedly lower percentage than in the general population (= 14% of families with children aged
50
51 0-7 years during 2003, when the initial data were collected; Statistics Finland, 2013). However, the
52
53 percentage of single parent families can be expected to be lower among the families of young infants.
54
55
56
57

58 Parental education was classified using a seven-point scale ranging from a basic level, 0 (*no*
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 *vocational education*), to advanced educational training, 6 (*higher-level university degree*). The
4
5 sample was fairly representative of the Finnish population (Statistics Finland, 2013). The distribution
6
7 of family educational level in the sample was as follows: 7% of mothers and 6% of fathers (general
8
9 population 6%) had no vocational education, 58% of mothers and 66% of fathers (general population
10
11 64%) had at least some vocational degree, and 35% of mothers and 29% of fathers (general population
12
13 29%) had a master's or higher university degree. Finnish families are typically dual-earner families
14
15 with both parents working full time (Salmi & Lammi-Taskula, 2014). State-funded parental leave lasts
16
17 up to 10 months of age, after which child home-care allowances are provided for the first 1 to 3 years.
18
19 Around 40% of mothers with children under the age of three years and 80% of mothers of children
20
21 aged between 3 to 6 years work outside the home (Salmi & Lammi-Taskula, 2014). Child care is
22
23 provided in day care centers or in family day care, the former of which is more commonly used (84%
24
25 vs. 16%; Kekkonen, 2014). Rates of day care attendance vary according to the child's age. Around
26
27 30% of one-year-olds, 50% of two-year-olds, 70% of three-year-olds, 75% of four-year-olds, and 80%
28
29 of five-year-olds are in day care. Family day care is more common in the youngest age groups.
30
31 Children have a right to attend pre-school education the year before their compulsory education starts
32
33 (the year they turn 6). Pre-school education is provided in day care centers and primary schools. The
34
35 majority (98%) of children attend pre-school education (Statistics Finland, 2013). Compulsory
36
37 schooling starts in the year of the child's seventh birthday.
38
39
40
41
42
43
44

45
46 There were small but significant differences in demographics between the children who had
47
48 data from the last two follow-ups at age 5;3 and first grade (*n* range 100-102 and 230-234) and those
49
50 who did not (*n* range 373-394 and 241-263): The participants in the last two follow-ups had slightly
51
52 older and more educated mothers (mother's age: 30.9 vs. 29.6 at 5;3, $p = .031$, $\eta_p^2 = .009$; 30.4 vs.
53
54 29.4 in first grade, $p = .039$, $\eta_p^2 = .009$; mother's education: 4.1 vs. 3.7 at 5;3, $p = .050$, $\eta_p^2 = .008$; 4.1
55
56 vs. 3.6 in first grade, $p = .002$, $\eta_p^2 = .020$). However, only maternal education in the sample at first
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 grade remained significantly different after correcting for multiple comparisons (Bonferroni
4
5 correction, nine comparisons). These results are in line with previous observations reported by
6
7
8 longitudinal studies of language that attrition tends to be lower among children with older and more
9
10 educated mothers (e.g., Henrichs et al., 2011; Reilly et al., 2010). No other significant differences
11
12 between the subsamples were found.
13
14

15
16 By the end of the study, two children (information was available for 338 children) had
17
18 received a diagnosis of language impairment and three children were reported as having broader
19
20 developmental difficulties. In addition, based on parent report, health care providers had observed
21
22 indications of delayed language development in 17 children (5.0 %). Parents reported the use of
23
24 speech and language therapy services for language-related difficulties (excluding articulation and
25
26 stuttering problems) for 11 (3.3 %) children. The discrepancy between the number of children with
27
28 diagnosed language impairment and those attending speech and language therapy services is probably
29
30 due to the service structure in Finland. Children do not need a formal diagnosis to be eligible for
31
32 specialist services. Families are referred to these services if any concerns arise during their annual
33
34 check-ups at their local child health care clinics. Very often, the first step is to see whether a more
35
36 intensive follow-up together with family guidance or a few visits to a speech and language therapist is
37
38 enough before referring the child for further assessments and formal diagnostic procedures.
39
40
41
42

43 44 **Measures**

45
46 **Early communication measure.** Early communication skills were assessed using the Finnish
47
48 version of the ITC of the CSBS-DP (Laakso, Poikkeus, & Eklund, 2011; Wetherby & Prizant, 2002).
49
50 The ITC is a parent-report screening tool that consists of 24 questions designed to measure relevant
51
52 prelinguistic milestones of early communication and language development in children aged 6 to 24
53
54 months. The questions are organized into three composites and cover several areas of development,
55
56 such as emotion and use of eye gaze, communication, and gestures (social composite, 13 questions);
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 sounds and words (speech composite, five questions); and understanding and object use (symbolic
4
5 composite, six questions). The ratings are either on a three-point scale (0 = not yet, 1 = sometimes, 2 =
6
7 often) or on scales that describe a series of numbers or ranges affording 0 to 4 points (e.g., 0 = none, 1
8
9 = 1-3, 2 = 4-10, 3 = 11-30, 4 = over 30). The Cronbach's α s over the age span of 6 to 18 months
10
11 ranged from .80 to .89, and by age (6, 9, 12, 15, and 18 months; n s = 191-320) from .68 to .73 for the
12
13 social composite, from .47 to .63 for the speech composite, and from .38 to .58 for the symbolic
14
15 composite. The variations in the alpha values by age are probably due to the fact that the questions for
16
17 each age are the same, meaning that some of the questions might behave differently at different age
18
19 stages (such as the number of words spoken or understood).
20
21
22
23

24 **Measures at 2 years of age.** Children's expressive vocabulary was assessed with the Finnish
25
26 version of the MacArthur-Bates Communicative Development Inventories Words and Sentences
27
28 (Fenson et al., 1994; Lyytinen, 1999). The checklist contains four subscales that measure vocabulary,
29
30 use of language, noun and verb inflections, and word combinations in children aged 16 to 30 months.
31
32 Three of these subscales were used in this study. In the vocabulary scale, the parent indicates which of
33
34 the predefined 595 words they have heard their child produce spontaneously. The words include
35
36 nouns, verbs and adjectives that are commonly used by children of this age. A total number of words
37
38 is calculated for each child. In the inflections scale, the parent indicates which of the 16 inflections
39
40 (e.g., plural, verb tenses) are present in the child's spontaneous speech. The sum of the noun and verb
41
42 inflections that the child uses is calculated for each child. In the third section, the parent writes
43
44 verbatim the three longest sentences they have heard their child produce. Average sentence length,
45
46 measured as morphemes, is calculated based on these three sentences.
47
48
49
50
51
52

53 **Measures at 3 years of age.** The children's single-word receptive vocabulary was assessed
54
55 with the Peabody Picture Vocabulary Test (PPVT; Dunn & Dunn, 1981). The PPVT consists of 166
56
57 words accompanied by black-and-white line drawings. The child hears a word and selects the picture
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 that corresponds to the word from an array of four pictures. Total score of correct answers was used in
4
5 the analyses.
6

7
8 Boston naming (Kaplan, Goodglass, & Weintraub, 1983) was used as a measure of single-
9
10 word expressive vocabulary. The task consists of 60 pictures that the child has to name. If the child
11
12 does not produce a word for the picture, he/she is prompted with a semantic cue. If the child fails to
13
14 produce the word, a phonological cue is given (e.g., the first two sounds of the word). The total
15
16 number of correct productions is calculated from the words the child produces either spontaneously or
17
18 with the semantic cue.
19
20

21
22 **Measures at 4;7.** Language and communication related concerns were assessed with the Five
23
24 to Fifteen questionnaire (FTF; Kadesjö et al. 2004). The FTF is a parent questionnaire developed for
25
26 the elicitation of symptoms and problems typical of ADHD and its comorbidities. The FTF comprises
27
28 181 statements related to behavioral or developmental problems. The language domain of the
29
30 questionnaire consists of 21 questions divided into three subscales. The comprehension subscale (five
31
32 questions) measures difficulties in understanding words, explanations and stories. The expressive
33
34 subscale (13 questions) measures difficulties in fluency, word retrieval and complexity of speech. The
35
36 communication subscale (three questions) measures difficulties in social communication and
37
38 narration. Ratings are made on a three-point scale (0 = does not apply, 1 = applies sometimes or to
39
40 some extent, 2 = definitely applies). Due to missing values for some items, the means of the subscales
41
42 were used in the analyses. The Finnish validation of the FTF for 5-year-olds ($n = 769$) reported the
43
44 reliability of the whole language domain to be .89 (Korkman, Jaakkola, Ahlroth, Pesonen, & Turunen,
45
46 2004). Cronbach's α s of .84 for comprehension, .84 for expressive, and .75 for communication have
47
48 been reported (Kadesjö et al., 2004). In the present data the corresponding values were .66, .87, and
49
50
51
52
53
54
55
56 .71, respectively.

57
58 **Language measures at 5;3.** The language measures were selected to cover various areas of
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 language ability in both the expressive and receptive domains, as suggested by Conti-Ramsden and
4
5 Durking (2012).
6
7

8 The Similarities (SI) subtest of the Wechsler Preschool and Primary Scale of Intelligence –
9
10 Revised (Wechsler, 1995) was used to assess verbal abstract reasoning and conceptualization abilities.
11
12 The test comprises three parts: In the first part, the child sees a stimulus picture and is asked to select a
13
14 compatible picture from an array of four pictures (six items); in the second part, the child completes a
15
16 sentence with an appropriate word (six items); and in the third part the child describes how two things
17
18 are alike (eight items).
19
20
21

22 A 30-item shortened version of the Peabody Picture Vocabulary Test – Revised (PPVT-R;
23
24 Dunn & Dunn, 1981) was used to assess the child’s single-word receptive vocabulary. The items were
25
26 selected on the basis of data drawn from another Finnish study, the Jyväskylä Longitudinal Study of
27
28 Dyslexia (see Lyytinen et al., 2004; Lyytinen, Erskine, Tolvanen, Torppa, Poikkeus, & Lyytinen,
29
30 2006) where the full-scale version of the PPVT-R was administered to the control group.
31
32
33

34 The Korpilahti Auditory Sentence Comprehension test (SC; Korpilahti 1996) was used as a
35
36 test for receptive grammar. The test assesses the ability to process semantic and syntactic information
37
38 in sentences. The test comprises 30 sentences that increase in complexity and make increasing
39
40 demands on verbal reasoning and auditory short-term memory. After each sentence the child is
41
42 presented with three pictures and asked to choose the one that goes best with the sentence.
43
44
45

46 The Verbal Fluency, Semantic categories test (VFS; NEPSY-II; Korkman, Kirk, & Kemp,
47
48 2008) assesses verbal productivity and vocabulary. The child is asked to generate as many words as
49
50 possible within specific semantic categories (animals, foods) in 60 s.
51
52

53 **Working memory measures at 5;3.** The working memory measures were selected to cover
54
55 the relevant subsystems of Baddeley’s (2003; 2012) model of working memory, following the
56
57 conceptualizations of Archibald & Gathercole (2006) and Petruccelli, Bavin, & Bretherton (2012).
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 The Digit Span subtest of the Wechsler Intelligence Scale for Children – Third Edition
4
5 (WISC-III; Wechsler, 1999) comprises two parts: In the first part, the child repeats a dictated series of
6
7 digits verbatim (forward part), and in the second part the child repeats the series backwards (backward
8
9 part). The series begin with two digits and increases in length with two trials at each length. As the
10
11 forward part is regarded as tapping the phonological loop and the backward part as tapping both the
12
13 phonological loop and the central executive (e.g., Vance, 2008), the two parts were treated as separate
14
15 measures in the analyses.
16
17
18
19

20 Nonword repetition (NWR) ability was assessed with the Repetition of Nonsense Words test
21
22 (NEPSY; Korkman, Kirk, & Kemp, 1997). In this test, the child imitates 16 nonwords that increase in
23
24 length from one (“nas”) to six (“skrikoflunaflistrop”) syllables. The nonwords conform to the
25
26 phonotactic rules of Finnish but are low in word likeness and phonotactic frequency. The test is
27
28 regarded as tapping the phonological loop along with other language-related processes such as speech
29
30 perception, phonological encoding and assembly, and articulation (Coady & Evans, 2008).
31
32
33

34 In the Sentence Repetition task (SR; NEPSY-II; Korkman et al., 2008), the child is read 17
35
36 sentences that increase in complexity and length, and asked to recall each sentence verbatim
37
38 immediately after it is presented. The task requires the integration of information from phonological
39
40 short-term memory with long-term linguistic knowledge, and thus is regarded as being a measure of
41
42 the episodic buffer, which is responsible for storing chunks of such integrated information (Baddeley,
43
44 2000; Boyle, Lindell, & Kidd, 2013).
45
46
47

48 **Measures in the first grade.** The children’s language and communication difficulties were
49
50 assessed with the Finnish version of the Children’s Communication Checklist – Second Edition
51
52 (CCC-2; Bishop, 2003; Norbury, Nash, Baird, & Bishop, 2004). The CCC-2 is a parent questionnaire
53
54 used to screen for general language impairments and pragmatic language impairment in children aged
55
56 4 to 16 years. The questionnaire includes four subscales that measure language abilities (speech,
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 syntax, semantics, and coherence) and four areas of pragmatics (inappropriate initiations, stereotyped
4 language, use of context, and nonverbal communication). The two additional subscales (social
5 relations and interests) were omitted in this study. Each scale comprises 5 questions on difficulties,
6 and 2 questions on strengths (reversed scale). Parents rate the frequency of their child's language and
7 communication behaviors on a four-point scale (0 = less than once a week, 1 = at least once a week,
8 not every day, 2 = once or twice a day, 3 = several times a day/always). The Cronbach's α s for the
9 separate subscales have been reported to be above .66 (Bishop, 2003). The α s in the current sample
10 ranged between .57-.87 for the separate subscales and the α s for the combined language scales and
11 combined pragmatics scales were .91 and .92 respectively.
12
13
14
15
16
17
18
19
20
21
22
23

24 **Data analyses**

25
26
27 The development of early communication skills was analyzed using a type of second-order
28 multivariate Latent Growth Curve modeling called the factor-of-curves model (Duncan, Duncan, &
29 Strycker, 2006, pp. 68-70; McArdle, 1988). Multivariate LGM is used to determine if development on
30 one behavior covaries with development in other behaviors and it provides a "more dynamic view of
31 the correlates of change, as development in one variable can be associated with development in
32 another variable" (Duncan et al., 2006, p.63). In the factor-of-curves model it is examined whether a
33 second-order factor adequately describes the covariances among lower order developmental functions
34 (Duncan et al., 2006, p.68).
35
36
37
38
39
40
41
42
43
44

45
46 The analyses were performed using the Mplus statistical package (version 7; Muthén &
47 Muthén, 1998-2010). The estimation method was the robust MLR which corresponds to the full-
48 information maximum likelihood (FIML). In FIML there does not need to be the same number of
49 items, observations, or variables for every individual as the log-likelihoods are written for each
50 individual based on the individual's observed data (e.g. see Enders, 2010, pp. 88-92; Graham &
51 Coffman, 2012, p. 282). The use of FIML over other methods such as listwise deletion is
52
53
54
55
56
57
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

recommended as FIML preserves key relationships among variables and better estimates the variability in the data yielding more valid results (see, Jeličić, Phelps, & Lerner, 2009). Thus, despite having different amount of data at different age stages, all available data between the ages 6 to 18 months was used ($n = 203-322$ at different ages, $n = 427$ in total) as it leads to improved accuracy of parameter estimates (Enders, 2010, p.92). The coverage of the elements in the covariance matrix is presented in Table SM4.

The goodness-of-fit of the estimated LGC models was evaluated using several fit indexes (χ^2 test, the Comparative Fit Index, the Tucker-Lewin Index, the Root Mean Square Error of Approximation, and Standardized Root Mean Square Error of Approximation; Hu & Bentler, 1999; Muthén & Muthén, 1998-2010). Specifications to the model were done based on the model modification indices and theoretical considerations. Modification indices above 4 were taken into account and each of them was considered from a theoretical standpoint. Only those indices that were deemed appropriate both statistically and theoretically were added to the model.

All analyses were conducted with raw data. As the follow-up subsamples were only partially overlapping, the regression analyses were conducted separately for each follow-up.

Results

A latent growth curve (LGC) model for early communication development

All correlations between the three ITC composites at different age stages are shown in Table SM3. All the successive measurements within the ITC composites correlated significantly with each other, as was expected due to the sequential nature of the data, and thus, were allowed to correlate with each other within the composites in the LGC model.

A LGC model for each of the three ITC composites (social, speech, symbolic) was estimated simultaneously. Based on visual inspection of the individual growth curves and the model modification indices, nonlinear growth was estimated. In the model specifications all loadings on first

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 order intercepts were fixed (at 1), while in the loadings of the first-order slopes, the first and last time
4
5 points were fixed (at 0, and at 4), and age 9, 12, and 15 month loadings were estimated freely (*1, *2,
6
7 *3). The modeling of unspecified trajectories using a two-factor model (only intercept and slope
8
9 instead of a specified model) was chosen as the unspecified model might be able to provide better
10
11 model fit and is somewhat easier to interpret. That is, the fitting of a quadratic and a cubic slope factor
12
13 (i.e., a specified model), would lead to 9 and 12 first-order factors, respectively, which would lead to
14
15 an unnecessarily complex model that would be more difficult to interpret and might lead to
16
17 convergence problems. In addition, it has been suggested that unless there are solid theoretical
18
19 justifications for another model, using unspecified model is recommended (see a simulation study by
20
21 Welch, 2007). In this type of modeling, instead of a predefined shape of growth (i.e., adding a
22
23 quadratic or cubic factor), the data is allowed to determine the shape of growth (Duncan et al., 2006,
24
25 pp.31-35).
26
27
28
29
30

31
32 The correlations between the first-order level factors and between the first-order growth
33
34 factors were significant ($r = .57-.81, p < .001$ between the social, speech, and symbolic level factors,
35
36 and $r = .48 - .67; p < .001 - .010$ between the social, speech, and symbolic growth factors). Thus, a
37
38 second-order factor structure (common level and common slope) was added to the model to describe
39
40 these relationships between the composite-specific first-order factors (i.e., explain the covariances
41
42 among the first-order factors; Duncan et al., 2006, pp. 68-69). The symbolic composite was used as
43
44 the reference scaling for the second order structure (fixed at 1; Duncan et al., 2006, p. 69; McArdle,
45
46 1988) and the other factor loadings were estimated freely.
47
48
49

50
51 The residual correlations were strong between the different measures at the same time point
52
53 (i.e., social, speech, and symbolic at age 9 month, age 12 months, and age 15 months) indicating that
54
55 there is some age-specificity in development at these ages that is not captured by the first- and second-
56
57 order factors. Thus, specific age factors were added to explain this between-individual variation that is
58
59
60

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

specific to the time points measured and not related to development over the measured time period.

These specific factors were not allowed to correlate with each other or with the first- and second-order factors. The model fitted the data well: $\chi^2(73) = 87.405$, $p = .120$, CFI = .991, TLI = .987, RMSEA = .021 and SRMR = .083.

Figure 2 depicts the LGC model and reports the standardized estimates. These estimates should be interpreted to depict effect sizes. In line with the observed means across the 6 to 18 month period (reported in Table 2), the LGC model showed growth throughout the measured time period in all three ITC composites, which was indicated by increases in the model produced mean values over time. The correspondence between the observed and the model estimated mean values was good. The first-order loadings on growth factors represent the individual differences present at a certain time point. Thus, a higher standardized loading for example at age 15 months compared to the loading at age 18 months in social and speech composites (see Figure 2) indicate that the largest individual differences are present at this age.

Early communication development and later language and communication skills

The model fit indices for the longitudinal models between the early LGC model and the follow-up measurements at ages 2, 3, 4;7, 5;3 and first grade are summarized in Table SM5.

The model modification indices suggested several skill- and age-specific pathways from the level of the speech composite, from the growth factor of the social and speech composites, and from the age-specific factor at 15 months of age. More specifically, the suggested pathways included: from the growth factor of the social composite to MCDI inflections at 24 months ($p = .040$), FTF expressive language at 55 months ($p = .217$), and the memory factor at 63 months ($p = .274$); from the level of the speech composite to MCDI inflections at 24 months ($p = .136$), the memory factor at 63 months ($p = .019$), and the first-grade language ($p = .034$) and communication ($p = .024$) factors; and from the growth factor of the speech composite to expressive vocabulary at 36 months ($p = .050$), FTF

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

1
2
3 expressive language at 55 months ($p = .063$), the memory factor at 63 months ($p = .002$), and the first-
4
5 grade language ($p = .007$) and communication ($p = .023$) factors. Age-specific paths were suggested
6
7 from the specific age factor at 15 months to MCDI vocabulary ($p = .012$) and inflections ($p = .024$) at
8
9 24 months, the memory factor at 63 months ($p = .090$), and the first-grade language ($p = .007$) and
10
11 communication ($p = .011$) factors. None of these paths were significant at the .001 level, and thus no
12
13 specific paths were added to the regression models.

5;3	SR	11.2	11.0	21.3	22.2	20.1					23.4	
7;9	CCC-II	27.8	25.6	40.9	41.6	36.9						58.8

Note. ITC = Infant-Toddler Checklist; MBCDI = MacArthur-Bates Communicative Development Inventories; MSL = Maximum Sentence Length; PPVT = Peabody Picture Vocabulary Test; FTF = Five to Fifteen; SI = Similarities; SC = Sentence Comprehension; VF = Verbal Fluency; DS = Digit span; NWR = Nonword Repetition; SR = Sentence Repetition; CCC-II = Children's Communication Checklist –Second Edition.

Running head: CONTINUITY OF COMMUNICATION AND LANGUAGE DEVELOPMENT

Table SM5

The Model Fit Indices for the LGC Model and the Regression Models of the Follow-Up Measurements.

Age	LGC model	χ^2	df	<i>p</i>	CFI	TLI	RMSEA	RMSEA 90% CI	SRMR	
12 to 18 months	Early communication development	87.405	73	0.1198	0.991	0.987	0.021	0.000 0.037	0.083	
Outcome variables										
2 years	MCDI: vocabulary, inflections, MSL	153.548	112	0.0056	0.979	0.971	0.029	0.017 0.040	0.091	
3 years	Boston, PPVT	119.435	99	0.0793	0.988	0.984	0.022	0.000 0.035	0.083	
4;7	FTF expressive, receptive, communication	136.459	112	0.0579	0.987	0.982	0.022	0.000 0.033	0.078	
5;3	Psychometric tests: Language, memory	258.160	207	0.0090	0.973	0.967	0.024	0.018 0.033	0.089	
1 st grade	CCC-II: Language, communication	236.476	206	0.0714	0.991	0.988	0.018	0.000 0.028	0.071	

Note. A nonsignificant chi-square test ($p > .05$), CFI and TLI values at or above .95, RMSEA below .06, and SRMR below .08 serve as guidelines for determining good model fit (Hu & Bentler, 1999; Marsh, Hau, & Wen, 2004). LGC = latent growth curve; CFI = comparative fit index; TLI = Tucker-Lewin index; RMSEA = root mean square error of approximation; CI = confidence interval; SRMR = standardized root mean square error of approximation; MCDI = MacArthur-Bates Communicative Development Inventories; MSL = Maximum Sentence Length; PPVT = Peabody Picture Vocabulary Test; FTF = Five to Fifteen; CCC-II = Children’s communication Checklist –Second Edition.
