1 **Abstract**

2 **Objective:** This study examined the effects of consistency tendency on the predictive power  
3 of the theory of planned behavior (TPB) in relation to physical activity behavior.

4 **Methods:** In this randomized controlled cross-over trial, we recruited 770 undergraduate  
5 students from Indonesia who were randomly assigned into two groups. Participants completed  
6 physical activity versions of TPB measures at T1 (baseline) and T2 (post 1 week), and the  
7 International Physical Activity Questionnaire at T3 (post 1 month). At T1 and T2, the TPB  
8 questions were either presented in ensemble-order (i.e., consistency tendency suppressed) or  
9 alternate-order (i.e., consistency tendency facilitated).

10 **Results:** The parameter estimates of the model ( $CFI > .92$ ,  $TLI > .90$ ,  $SRMR < .08$ ,  $RMSEA$   
11  $< .08$ ) aligned with the tenets of TPB. As compared to ensemble-order, a TPB measured in  
12 alternate-order yielded stronger cross-sectional relationships, but this pattern did not appear in  
13 the prospective relationships in TPB (i.e., intention/ perceived behavioral control and  
14 behavior).

15 **Conclusions:** Consistency tendency inflated the factor correlations of cross-sectionally  
16 measured TPB variables, but the inflation was not observed in the prospective prediction of  
17 behavior. Health psychology questionnaires with items presented in ensemble order may  
18 represent a viable means of reducing the confounding effect of consistency tendency.

19 **Keywords:** Consistency motif; proximity effect; socratic effect; common method variance;  
20 response bias; general response tendency.

21

## Consistency Tendency and The Theory of Planned Behavior:

### A Randomized Controlled Crossover Trial in Physical Activity Context

The theory of planned behavior (TPB) is one of the most widely-used health psychology frameworks in the explanation of individuals' behaviors in physical activity (Hagger, Chatzisarantis, & Biddle, 2002; Hausenblas, Carron, & Mack, 1997) as well as other health settings (Godin & Kok, 1996; McEachan, Conner, Taylor, & Lawton, 2011). The measurement of TPB constructs has predominantly relied on self-reported questionnaires in which the findings could be confounded to some extent by response bias, common method effects, and other methodological artifacts (Budd, 1987; Budd & Spencer, 1986; Courneya, Conner, & Rhodes, 2006; Rhodes, Matheson, & Blanchard, 2006; Rhodes, Matheson, Blanchard, & Blacklock, 2008; Rhodes, Matheson, & Mark, 2010). In particular, *common method bias* is an inherently unobservable phenomenon that captures the variance attributed to measurement method rather than the variance of the theoretical construct (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003; Podsakoff, MacKenzie, & Podsakoff, 2012; Richardson, Simmering, & Sturman, 2009). It is, therefore, undesirable if common method variance induces systematic errors that not only confound the validity of measurement of TPB variables, but also the explanatory power of the theory in relation to behavior change (Budd, 1987; Budd & Spencer, 1986; Courneya et al., 2006; Rhodes et al., 2006; Rhodes et al., 2010). In this study we sought to examine the effects of a common method bias, namely, consistency tendency (Chan, Ivarsson, et al., 2015), on the parameter estimates of the TPB in the prediction of physical activity.

### **Theoretical Explanation of Consistency Tendency**

Consistency tendency (also known as Socratic effect) is the tendency that consecutive items in a questionnaire are answered in consistent way, and so it is speculated that this common method bias may induce artificial covariance between predictors and criterion

1 variables (Salancik, 1984; Salancik & Pfeffer, 1977). Researchers have been aware of this  
2 method effect and have offered critical insights into how consistency tendency could  
3 confound research findings of questionnaire-based research (Chan, Ivarsson, et al., 2015;  
4 Cronbach, 1946; Doty & Glick, 1998; Podsakoff et al., 2012; Salancik, 1984). For decades  
5 there has been debate over the extent to which factor correlations are caused by the similarity  
6 or commonality of the form of measurement rather than the actual between-factor  
7 relationships (Cronbach, 1946; Doty & Glick, 1998; Lindell & Whitney, 2001; Warren &  
8 Halpern-Manners, 2012; Weijters, Geuens, & Schillewaert, 2009).

9         Cronbach (1946, 1950) first identified the tendency, known as *response sets*, of  
10 individuals to respond to items in a questionnaire according to the test format. The theoretical  
11 foundation of response sets is derived from the psychology literature that explains how  
12 individuals unconsciously establish frames or points of reference when making judgments or  
13 selections in a questionnaire, and the established referencing frames tend to be retained for  
14 subsequent assessments (Sherif & Cantril, 1945, 1946). According to response sets theory  
15 (Cronbach, 1946, 1950), response sets can cause a person to “give different responses to test  
16 items than he [or she] would when the same content is presented in a different form”  
17 (Cronbach, 1946, p. 146). Indeed, it may also make an individual offer similar responses to  
18 test items of different content “when similar situations are presented” (Cronbach, 1950, pp.  
19 14-15), then “response set scores are significantly correlated” because of response sets rather  
20 than the true relationships between the factors. More recent literature refers to this specific  
21 type of response set as consistency tendency (Salancik, 1984; Salancik & Pfeffer, 1977),  
22 consistency motif (Podsakoff et al., 2003; Podsakoff & Organ, 1986), or Socratic effect  
23 (Henninger & Wyer, 1976; Wyer, 1974).

24         The origin of consistency tendency is believed to come from individuals’ awareness of  
25 their own responses to questions (Budd, 1987; Budd & Spencer, 1986; Salancik, 1984;

1 Salancik & Pfeffer, 1977). This awareness may lead to unconsciously answering consecutive  
2 questions consistently because responses themselves include salient information that could  
3 constrain participants' subsequent responses in a test battery (Salancik, 1984; Salancik &  
4 Pfeffer, 1977). It is somewhat consonant with the mere measurement effect evidenced in the  
5 recent psychology literature (Godin, Belanger-Gravel, Amireault, Vohl, & Perusse, 2011;  
6 Mankarious & Kothe, 2015; Morwitz & Fitzsimons, 2004) that explains how the act of asking  
7 questions about a person's intention can itself change behavior. The mere measurement effect  
8 has been attributed to the increased saliency and accessibility of the thoughts, memories,  
9 attitudes, and response choices associated with the behavior after responding to items  
10 concerning a person's intention (Mankarious & Kothe, 2015; Morwitz & Fitzsimons, 2004).  
11 Similarly, recent research on the longitudinal effect of panel conditioning suggests that  
12 measuring attributes (e.g., attitudes) could change participants' responses toward the  
13 attributes in follow-up measures (Sturgis, Allum, & Brunton-Smith, 2009; Warren &  
14 Halpern-Manners, 2012), so it might imply that the after-effect of item responses could  
15 operate at the survey level and affect participants' subsequent responses within the  
16 questionnaire (Duan, Alegria, Canino, McGuire, & Takeuchi, 2007). In general, the literature  
17 appears to support the proposition that participants' responses in the measure of attitude and  
18 behavior could be affected by their prior response pattern (Godin et al., 2011; Mankarious &  
19 Kothe, 2015; Morwitz & Fitzsimons, 2004; Sturgis et al., 2009; Warren & Halpern-Manners,  
20 2012).

### 21 **Consistency Tendency and Response Order**

22         Researchers have proposed several methods for controlling the effects of consistency  
23 tendency, such as placing correlational markers, factor analysis, and counter-balancing the  
24 item-order (Lindell & Whitney, 2001; Podsakoff et al., 2003; Richardson et al., 2009). For  
25 instance, physical separation can reduce the consistency tendency by minimizing the saliency

1 of contextual cues that might exist in the previous measurement, and more importantly, it  
2 impairs respondents' ability to use information or answers from previous questions to inform  
3 their responses (Podsakoff et al., 2003). Podsakoff and colleagues (2003) suggested that  
4 temporal or proximal separation could be done by intentionally placing a time-lag or physical  
5 gap between the measurements of different variables. In this case, response bias could be  
6 reduced because (1) short term memory is less likely to hold the information from previous  
7 responses; (2) the perceived relevance of previous items would be diminished; and (3)  
8 individuals might have impaired ability or motivation to use their prior responses for  
9 completing subsequent items.

10 In support of the proposition about the temporal or proximal effects of response sets,  
11 Hui and Triandis (1985) consistently found in three studies (i.e., with different instruments)  
12 that the inter-item correlations were stronger between adjacent items than the items that were  
13 further apart. In a similar regard, a qualitative investigation of the proximity effect model  
14 (Weijters et al., 2009) showed that when respondents answered two items that were close to  
15 each other, they tended to perceive them as being related or that the second item was  
16 redundant or repetitive, so they were likely to carry the same beliefs to answer the items. Such  
17 a behavioral pattern occurs because representation of the previous item in highly-accessible  
18 short-term memory gives the respondent the perception that the next question was similar or  
19 alike even if they were not identical. Similarly, the meta-analysis of common method variance  
20 by Doty and Glick (1998) found that time-lag was a significant source of common method  
21 bias that negatively correlated with the within-study factor correlations.

22 As a complement to this evidence, there have been attempts in previous research to  
23 examine the effect of item-ordering within questionnaires (Duan et al., 2007; Holbrook,  
24 Krosnick, Moore, & Tourangeau, 2007; Hui & Triandis, 1985; McClendon, 1991; Stone &  
25 Gueutal, 1984; Weijters et al., 2009). However, these studies did not test how the item-order

1 moderated the strength of relationships between theoretically linked factors. The only  
2 exception was the work by Budd and colleagues (Budd, 1987; Budd & Spencer, 1986)  
3 concerning response bias in relation to the theory of reasoned action (Ajzen & Fishbein,  
4 1980), which represented the preceding theory of the TPB. It was found that the inter-factor  
5 correlations of the theory of reasoned action (e.g., attitude, subjective norm, and intention)  
6 were stronger when the items were presented in a non-random-(item)order (i.e., an item of  
7 one factor was followed by an item of another factor) than that in a random-(item)order  
8 (Budd, 1987; Budd & Spencer, 1986). It was argued that when the items were presented in a  
9 non-random logical order, the format of the questionnaire artificially made respondents  
10 aware of the factor relationships, which further brought about a response consistency and  
11 inflated the inter-factor correlations reported with respect to the theory of reasoned action  
12 (Budd, 1987; Budd & Spencer, 1986). However, these studies were limited by having a quasi-  
13 experiment with two-group comparison design, in which the authors did not take inter-item  
14 distance into account within the questionnaire design and interpretation of study findings.  
15 Therefore, the findings of Budd and colleagues (Budd, 1987; Budd & Spencer, 1986) were  
16 unable to reveal if a consistency tendency was initiated by the inter-item distance of the  
17 questionnaire variables.

18         As far as we know, there has only been one recent investigation that formally and  
19 experimentally examined the effects of consistency tendency on factor correlations by  
20 manipulating the inter-item distance in a questionnaire (Chan, Ivarsson, et al., 2015). The  
21 study employed a two-wave two-arm randomized control cross-over design to examine if the  
22 parameter estimates in the motivational process model (i.e., autonomy support → autonomous  
23 motivation → intention) of self-determination theory (Deci & Ryan, 1985), were moderated  
24 by the inter-item distance. In line with the consistency tendency effect, the parameter  
25 estimates were stronger when items were arranged in an *alternate-order* than in *ensemble-*

1 *order*. Although the differences were not statistically significant, potentially due to the small  
2 sample size and data attrition, it was argued that the effect of consistency tendency in an  
3 *alternate-order* would be more salient (due to shortened inter-item distance between factors)  
4 when compared to an *ensemble-order* (due to lengthened inter-item distance between factors).  
5 Nevertheless, the study was limited because there were no inclusion of behavioral assessment  
6 and prospective follow-up, so it was unclear how consistency tendency could moderate the  
7 prospective relationship between intention and behavior. More importantly, the study only  
8 applied self-determination theory (Deci & Ryan, 1985) in the context of sport injury  
9 prevention, and so the effects of consistency tendency on the measures of other classic health  
10 psychology theories in relation to health behavior measures are currently unknown.

11 In sum, research over the years has attempted to examine response bias due to  
12 questionnaire format and structure (Podsakoff et al., 2003; Podsakoff et al., 2012; Richardson  
13 et al., 2009). Indeed, it has been increasingly recognized that one's propensity to display a  
14 response tendency could substantively (i.e., in non-trivial ways) interfere with the findings  
15 derived from health psychology measures (Chan, Ivarsson, et al., 2015). Previous studies have  
16 not formally examined 'method variance' by using inter-item distance to manipulate  
17 consistency tendency, and tested how this cognitive bias may affect the predictive power of  
18 the TPB (Ajzen, 1985).

### 19 **Present Study**

20 To address these research gaps, the present study examined the effects of consistency  
21 tendency on the pathways of the TPB in the physical activity context, using a 3-wave  
22 randomized cross-over trial with 1-month prospective follow-up of behavior. According to  
23 the tenets of the TPB (Ajzen, 1985) and its research findings in physical activity settings  
24 (Hagger et al., 2002; Hausenblas et al., 1997), the social cognitive variables of attitude,  
25 subjective norm, perceived behavioral control are positive predictors of intention which in

1 turn predict future engagement of physical activity. Perceived behavioral control (PBC) is  
2 also positioned as a direct predictor of behavior (i.e., unmediated by intention). Based on  
3 previous literature about consistency tendency (Henninger & Wyer, 1976; Salancik, 1984;  
4 Salancik & Pfeffer, 1977; Wyer, 1974), and the findings related to inter-item separation (Hui  
5 & Triandis, 1985; Weijters et al., 2009), we hypothesized that positive pathways of TPB  
6 would be stronger in the questionnaire with alternate-order (consistency tendency facilitated)  
7 as compared to that in an ensemble-order (consistency tendency suppressed). We further  
8 hypothesized that the inflations would only apply to the cross-sectional relationships in this  
9 study but not the prospective relationships that were assessed in relation to the TPB.<sup>1</sup> A time-  
10 lag or temporal gap was expected to reduce common method variance (vis-à-vis the saliency  
11 of previous measurement) on subsequent assessments (Podsakoff et al., 2003).

## 12 **Methods**

### 13 **Participants and Study Protocol**

14 Upon the ethical approval from the Institutional Review Board of the first author's  
15 institution [UW 18-523] and local ethics committee of the third author, we recruited 770  
16 undergraduate students of social and political science from Indonesia (mean age = 19.12, *SD*  
17 = 1.28, range = 16 to 30; 34.8% male; response rate = 81.99%). Based on the criteria of the  
18 International Physical Activity Questionnaire research committee (IPAQ; 2005), participant  
19 who had high, moderate, or low level of physical activity<sup>2</sup> were respectively 11.4%, 30.1%,

---

<sup>1</sup>In the current study, cross-sectional relations were assessed between attitude, subjective norm, PBC, and intention; whereas prospective relations were measured between PBC, intention, and physical activity.

<sup>2</sup>The criteria of high physical activity: (a) vigorous-intensity activity on at least 3 days achieving a minimum total physical activity of at least 1500 MET-minutes/week; or (b) 7 or more days of any combination of walking, moderate-intensity, or vigorous-intensity activities achieving a minimum total physical activity of at least 3000 MET-minutes/week. The criteria of moderate physical activity: (a) 3 or more days of vigorous-intensity activity of at least 20 minutes per day; or (b) 5 or more days of moderate-intensity activity and/or walking of at least 30 minutes per day; or (c) 5 or more days of any combination of walking, moderate-

1 and 58.4%. A large proportion (70.3%) participated in various leisure-time physical activity  
2 (e.g., jogging, running, swimming, soccer, badminton, volleyball, fitness training, cycling).

3 Before the start of the study, participants signed informed consent forms (i.e., to  
4 acknowledge their understanding of voluntary participation, rights of withdrawal, and  
5 confidentiality of data). They were randomly assigned into either Group 1 ( $n = 384$ ) and  
6 Group 2 ( $n = 386$ ) by computer balloting, and were blinded from the group allocation.  
7 Following a 3-wave cross-over design in this study, Group 1 completed the physical activity  
8 version of TPB measures in alternate-order and ensemble order, respectively at T1 (baseline)  
9 and T2 (post 1 week), and Group 2 did so in the opposite sequence (T1 = ensemble order, T2  
10 = alternate-order). Both groups completed the follow-up questionnaire of physical activity at  
11 T3 (post 1 month). The questionnaire was translated into Indonesian with the translate-back-  
12 translate procedure of Hambleton (2005) in a team of two Indonesian-English bilingual  
13 speakers and a psychologist with extensive research experience in applying TPB cross-  
14 culturally.

## 15 **Measures**

16 **TPB Variables.** We used the physical activity version (Chan, Yang, et al., 2015) of  
17 standard TPB measures (Ajzen, 2002) to assess attitude, subjective norm, PBC, and intention  
18 of engaging in adequate physical activity. Clear definition of “adequate physical activity for  
19 adults” was based on the public health guidelines recommended by the World Health  
20 Organization (2010). This target was provided at the top of the TPB scale for instruction. To  
21 make the item-order changeable without affecting the presentation of the scale, we made sure  
22 the items could be read independently by presenting items in full form (i.e., without shared  
23 item stem), using a 7-point Likert scale for each item. The data derived from TPB measures

---

intensity, or vigorous intensity activities achieving a minimum total physical activity of at least 600 MET-minutes/week. Individuals who did not meet the criteria for moderate or high were considered to have low levels of physical activity.

1 displayed sound reliability, as reflected by Omega coefficients [ $\omega$ ] (McDonald, 1970) ranging  
2 from .728 to .919. Internal consistency values were in general higher when the items were  
3 presented in ensemble order ( $M\omega = 0.85$ ) than alternate-order ( $M\omega = 0.80$ ). See Appendix A  
4 for all the items and anchors used with the TPB measures.

5 **Physical Activity.** We used the short-form of the International Physical Activity  
6 Questionnaire (IPAQ; Craig et al., 2003) to assess the physical activity levels at T3. IT has  
7 been shown that the short-form of IPAQ produces reliable responses that are reflective to  
8 objectively measured physical activity (Ekelund et al., 2006). Participants reported their  
9 physical activity in terms of “how many days in a week” and “how much time per day” they  
10 spent on respectively vigorous and moderate intensity physical activity, and walking. We  
11 converted the scorings of IPAQ into a single indicator of metabolic equivalent of task (MET)-  
12 minutes/week according to the guideline of IPAQ research committee (2005).

### 13 **Manipulation of Consistency Tendency**

14 The primary manipulation of this study was item-order of the study variables  
15 presented in the questionnaire. Each item was displayed in a standardized format with  
16 consistent fonts in which the question was placed at the top, and a seven-point Likert scale  
17 and its anchors were independently presented below (see Figure 1 as an example). The order  
18 of presenting the questionnaire items followed one of two different sequences. In ensemble-  
19 order, all the items of one construct were presented sequentially before the next construct;  
20 whereas in alternate-order, we inter-mixed the items such that one item designed to measure a  
21 construct was followed by a separate item designed to assess another construct. As some of  
22 the TPB variables (i.e., intention and subjective norm) had fewer items, we placed two 7-  
23 point Likert scale items related respectively to the frequency and effort of “doing physical  
24 activity in the last 2 weeks” to make the inter-mixing of items more balanced across the TPB  
25 variables in the alternate-order questionnaire, and these two items were also presented at the

1 end of the ensemble order questionnaire. The average inter-item distance (i.e., average  
2 distance between the items of distinct constructs) in ensemble-order questionnaire (7.34 item-  
3 units,  $SD = 1.77$ ;  $t(30) = 1.00$ ,  $p < .001$ , Cohen's  $d = .52$ ) was significantly higher than that of  
4 the alternate-order questionnaire (i.e., 2.25 item-units,  $SD = 1.56$ ).

5 **INSERT FIGURE 1 ABOUT HERE**

## 6 **Statistical Analysis**

7 We examined the effects of item-order between groups and within groups over time on  
8 the parameter estimates in the hypothesized model by employing structural equation modeling  
9 with Mplus version 8.1 (Muthén & Muthén, 1998-2017) using the robust maximum  
10 likelihood estimator (MLR). Missing data were handled by the full information maximum  
11 likelihood (FIML) estimator, which provided unbiased estimates under the assumption of the  
12 data missing at random (Enders, 2010). We relied on goodness-of-fit indices to evaluate  
13 model fit, given the known oversensitivity of the chi-square test of exact fit to sample size and  
14 minor model misspecifications (Marsh, Hau, & Grayson, 2005). Conventional fit indices were  
15 used to evaluate the model fit in the confirmatory factor analyses, such as the comparative fit  
16 index (CFI), Tucker-Lewis Index (TLI), the root mean square error of approximation  
17 (RMSEA), and standardized root mean square residual (SRMR). Traditional cut-off criteria  
18 with CFI and TLI values of .90 and RMSEA and SRMR values of .08 were used to indicate  
19 acceptable fit (Marsh, 2007). We computed the statistical power of each model we ran using  
20 MacCallum, Browne, and Sugawara (1996)'s algorithm. A statistical power of .80 or above  
21 was expected to support the adequacy of the sample size in each model (MacCallum et al.,  
22 1996).

23 Initially, we ran single-group structural equation models to examine goodness of fit of  
24 the measurement models at each time point within each group. To examine the effects of  
25 group assignment, invariance tests were conducted between Group 1 and Group 2 at T1 and

1 T2. To examine the effects of time, invariance tests were performed between T1 and T2 for  
2 each group. We initially built a baseline model with no constraints to examine configural  
3 invariance across groups and time, and then progressively constrained the parameter estimates  
4 to be equal between the groups or across time to test invariance of the measurement model.  
5 We followed the recommendations from Little (2013) and constrained the factor loadings and  
6 then indicator intercepts to examine metric invariance and scalar invariance, respectively. We  
7 adopted Chen's (2007) criteria of  $\Delta CFI < .01$  and  $\Delta RMSEA < .015$  as an indication of  
8 measurement invariance. Differences in the strength of the factor correlations between T1 and  
9 T2 within groups and between groups at T1 and at T2 were evaluated using the Wald test of  
10 parameter equalities (Buse, 1982). Between-group differences of predictors T1 and T2 in the  
11 predictive ability of physical activity at T3 was also evaluated using the Wald test of  
12 parameter equalities. The significance level was set to 0.05.

### 13 **Results**

14 The responses of the study variables were within the normal range, skewness and  
15 kurtosis values were between -1 and 1 for all variables except for physical activity that had a  
16 skewness value of 2.20 and a kurtosis value of 6.77. Of the initial 770 respondents, 694  
17 responded at T2, and 421 provided physical activity data at T3. Descriptive statistics are  
18 provided in Table 1. As displayed in Table 2, the model fit indices indicated that the  
19 measurement models had an adequate fit to the data within each group at each time point. The  
20 results also showed that the model was invariant within groups over time and between groups  
21 at each time point, as indicated by  $\Delta CFI$  and  $\Delta RMSEA$  of less than .01 and .015, respectively,  
22 in models with equality constraints imposed on the factor loadings and intercepts over time or  
23 across groups. Statistical power of the models ranged from .95 to .99, indicating adequacy of  
24 the sample size required for the complexity of the model.

25 **INSERT TABLE 1 AND 2 ABOUT HERE**

1 consistency tendency did not moderate the prospective relationships that we examined in this  
2 study. However, with a cross-over design, we managed to mirror the effects of T1 in T2 when  
3 the other group received the opposite treatment, so the effects of consistency tendency on  
4 cross-sectional relationships of TPB appeared to be highly robust.

5         These interesting findings were in line with the preliminary findings of Chan and  
6 colleagues (2015), and the literature regarding common method bias (Podsakoff et al., 2003;  
7 Podsakoff et al., 2012), consistency tendency (Salancik, 1984; Salancik & Pfeffer, 1977), and  
8 the Socratic effect (Henninger & Wyer, 1976; Wyer, 1974). The results may also explain why  
9 the inter-factor correlation of the social cognitive variables were inflated when they were  
10 aligned in a logical manner (Budd, 1987; Budd & Spencer, 1986). Our findings have  
11 important implications for questionnaire-based research in health psychology, as it was  
12 demonstrated that the covariance between two positively correlated variables (e.g., variable A  
13 and B) could be artificially inflated when the items of both factors were presented in  
14 alternate-order, and where inter-item distance (i.e., physical separation) was reduced. While  
15 temporal separation has often been used in various fields of psychology for reducing common  
16 method variance in questionnaire-based research (e.g., Chan & Hagger, 2012; Chan, Hagger,  
17 & Spray, 2011; Hagger, Chatzisarantis, Barkoukis, Wang, & Baranowski, 2005; Hagger,  
18 Chatzisarantis, Culverhouse, & Biddle, 2003), our findings suggest that researchers should  
19 *also* pay particular attention to the confounding effects of the proximity of the items *within* a  
20 given questionnaire.

### 21 **How to Minimize Consistency Tendency?**

22         To reduce the effect of consistency tendency, it is important to make sure that  
23 participants do not assume that consecutive items or study variables in a health psychology  
24 questionnaire are related or repetitive, and avoid relying on the previous responses to answer  
25 the next questions (Podsakoff et al., 2003; Weijters et al., 2009). The use of temporal or

1 proximal separation may be an effective solution for reducing the consistency tendency. Other  
2 methods such as placing a time gap, section break, highlighting the distinct or common  
3 features of the items (e.g., item stem), might also help as they may reduce participants'  
4 cognitive burden of questionnaire completion (Chan, Ivarsson, et al., 2015; Krosnick, 1991;  
5 Podsakoff & Organ, 1986; Weijters et al., 2009). However, researchers should be careful  
6 when randomizing item-order because the effect of consistency tendency is unlikely to be  
7 neutralized but rather factors could correlate more highly with their neighboring items or  
8 factors than those located further apart (Hui & Triandis, 1985; Podsakoff et al., 2003), leading  
9 to heightened random measurement error in the questionnaire (Budd, 1987; Budd & Spencer,  
10 1986).

### 11 **Study Limitations and Unexplored Issues of Consistency Tendency**

12         Balanced against the unique perspective provided by the present study, limitations  
13 should also be highlighted and addressed in future work. First, although our hypothesis was  
14 supported by non-significant between- and within-subject differences in prospectively  
15 measured relationships, the results could plausibly be due to the fact that both intention and  
16 PBC failed to significantly correlate with physical activity, and the effects of the predictions,  
17 in some group/ timepoints, were smaller than the meta-analytic findings derived from TPB  
18 research in relation to the explanation of health behaviors (Hagger & Chatzisarantis, 2009b;  
19 Hagger et al., 2002; McEachan et al., 2011). This could conceivably be explained by the  
20 manipulation of participants' consistency tendency or inter-item distance that interfered with  
21 the prospective prediction. It might also be plausible that the target behavior in TPB (i.e.,  
22 adequate physical activity) and the measurement of physical activity in IPAQ (i.e., time spent  
23 in various level of physical activity in the last seven days) were somewhat incompatible.  
24 Future tests should explore if the compatibility of the behavioral components within a  
25 questionnaire is related to factor correlations or consistency tendency. Despite being

1 statistically non-significant, the magnitude of the prospective intention → physical activity  
2 association appeared to be larger when the items were presented in an ensemble order ( $\beta_{T1} =$   
3  $0.170$ ,  $\beta_{T2} = 0.169$ ) compared to the alternate-order ( $\beta_{T1} = -0.070$ ,  $\beta_{T2} = 0.028$ ), and this  
4 pattern was consistent across both groups/timepoints. Indeed, for the relationship between  
5 PBC and behavior, it was generally not significant except when PBC was measured in  
6 alternate-order in T1. In fact, PBC forms a direct link to behavior because it is proposed to be  
7 a proxy measure of control over certain behaviors that demand heavily on resources,  
8 opportunity, and barriers (Ajzen & Madden, 1986; Hagger et al., 2002). The inconsistent  
9 finding of this direct link could be due to the possibility that the mediation of intention may  
10 attenuate the relationship between PBC and behavior (Ajzen, 1985), or the effect of  
11 consistency tendency in this study. Further studies should resolve this muddle by  
12 investigating if the consistency tendency effect only affects the predictive power of certain  
13 types of TPB variables or type of questionnaire format, and the introduction of alternative  
14 measures or criterion variables of physical activity (e.g., objective measurement by  
15 accelerometers or pedometers, implicit association test) or testing the consistency tendency  
16 effect in another health contexts may also be warranted (Chan, Ivarsson, et al., 2015).

17         The present study only looked at the relationships between positively linked factors, so  
18 we still know very little about how consistency tendency would affect the relationships  
19 between unrelated or negatively related constructs (see Hagger et al., 2007). The findings of  
20 Weijters and colleagues (2009) showed that proximity of items inflated the correlation  
21 between theoretically unrelated items, and reduced the correlation between a pair of reverse-  
22 scored, theoretically negatively-related items. In our study, the TPB variables were expected  
23 to be positively correlated (Ajzen, 1985), so we were unable to ascertain whether consistency  
24 tendency might moderate the correlations between factors that are expected to be negatively  
25 correlated or unrelated. Future studies may consider testing whether or not consistency

1 tendency results in either (a) the effects of negative predictors on dependent constructs being  
2 less negative, or (b) unrelated constructs displaying (unfounded) correlations (Hagger et al.,  
3 2007), by including or integrating additional variables from other psychological frameworks.  
4 Similarly, some psychometric instruments contain inverted items that are intentionally  
5 designed to tap the opposite valence of the intended dimensions (Hagger et al., 2007; Weijters  
6 et al., 2009). Yet, the questionnaires used in the present study did not consist of inverted or  
7 negatively-worded items. Moreover, other method effects such as yes-saying and naysaying  
8 effects, recency and primacy effects, and scaling response options may take place in a health  
9 psychology questionnaire (Chan, Ivarsson, et al., 2015; Courneya et al., 2006; Rhodes et al.,  
10 2006; Rhodes et al., 2008; Rhodes et al., 2010). Therefore, it would be important for further  
11 studies to evaluate the extent to which other method effects could moderate the effect of  
12 consistency tendency on item or factor covariance (Richardson et al., 2009).

13 Finally, it is important to point out that we did not include a measurement point of  
14 TPB variables at T3 where both groups completed the TPB questions in the same item-order.  
15 Recent research in the health psychology has adopted cross-lagged panel designs to examine  
16 the causal relationship between longitudinally assessed psychological variables (Lindwall,  
17 Larsman, & Hagger, 2011; Marsh & Perry, 2005). It would be highly interesting to test the  
18 effects of consistency tendency on cross-lagged pathways in longitudinal studies. This may  
19 reveal how consistency tendency could moderate the change of TPB variables and behavior  
20 over time.

## 21 **Conclusion**

22 Self-reported questionnaires with an arbitrary item-order is one of the most commonly  
23 adopted research methods of psychological and behavioral assessment in the field of health  
24 psychology (Andersen, McCullagh, & Wilson, 2007; Godin et al., 2010; Hagger &  
25 Chatzisarantis, 2009a; Mankarious & Kothe, 2015), but the measurement responses could be

1 confounded by common method bias. Our study demonstrated how the consistency tendency  
2 could moderate the strength of the pathways of the TPB in the prediction of physical activity.  
3 Inter-mixing the items may facilitate common method bias within TPB research, which  
4 results in artificially inflated cross-sectional factor correlations (i.e., attitude/ subjective norm/  
5 PBC → intention). Consistency tendency does not appear to inflate prospective (i.e., intention  
6 → behavior) relationships in TPB. Health psychology researchers should be mindful of the  
7 confounding effect of consistency tendency when designing questionnaires for the assessment  
8 of psychological and behavioral variables. It is important to make sure that research  
9 participants do not assume that consecutive items in questionnaires are repetitive or related to  
10 previous items. From a measurement development perspective, the inclusion of physical gaps  
11 (e.g., section breaks, page breaks) and temporal separation between measures (e.g., short  
12 breaks, time gap) might be effective strategies to reduce common method bias induced by  
13 consistency tendency.

*Note.* Norm = subjective norm; PBC = perceived behavioural control; PA = physical activity.

\**p* < .05

Appendix A  
Item-content and item-order of the scale at T1 and T2

		Anchors	Item- order – Ensemble	Item- order – Alternate
<b>Intention</b>				
1	I intend to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	1	1
2	I will try to put great effort into doing adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	2	5
3	I plan to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	3	9
<b>Subjective Norm</b>				
4	Most people who are important to me think that I should do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	4	2
5	It is expected of me that I do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	5	6
6	The people in my life whose opinions I value would approve me to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	6	10
<b>Perceived Behavioral Control</b>				
7	It is possible for me to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	7	3
8	If I want to I could do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	8	7
9	I have complete control over how to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	9	11
10	It is completely down to me to decide to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	10	14
11	It is easy for me to do adequate physical activity in the forthcoming month.	1 “Strongly Disagree” – 7 “Strongly Agree”	11	18
<b>Attitude</b>				
12	For me doing adequate physical activity in the forthcoming month would be ...	1 “Extremely Harmful” – 7 “Extremely Beneficial”	12	4
13	For me doing adequate physical activity in the forthcoming month would be ...	1 “Extremely Unpleasant” – 7 “Extremely Pleasant”	13	8
14	For me doing adequate physical activity in the forthcoming month would be ...	1 “Extremely Worthless” – 7 “Extremely Valuable”	14	12
15	For me doing adequate physical activity in the forthcoming month would be ...	1 “Extremely Bad” – 7 “Extremely Good”	15	15
16	For me doing adequate physical activity in the forthcoming month would be ...	1 “Extremely Unenjoyable” – “Extremely Enjoyable”	16	17
17	How frequent do you do adequate leisure-time physical activity in the last 2 weeks?	1 “Never” – 7 “Very Often”	17	13
18	How much effort do you put into doing adequate leisure-time physical activity in the last 2 weeks?	1 “Minimum Effort” – “Maximum Effort”	18	16

*Notes.* Item 16 was not included in the analyses because of weak factor loadings and inter-item correlations with the other attitude items.

## Appendix B

*Between-Group Comparisons of the Effects of TPB Variables at T1 and T2 on PA Behavior at T3 (While Controlling for PA Behavior at T1) Using Wald Test of Parameter Equalities (Standardized Coefficients are Presented)*
