Abstract. There is a large body of evidence that atomic nuclei can undergo octupole distortion and assume the shape of a pear. This phenomenon is important for measurements of electric-dipole moments of atoms, which would indicate CP violation and hence probe physics beyond the Standard Model of particle physics. Isotopes of both radon and radium have been identified as candidates for such measurements. Here, we have observed the low-lying quantum states in 224Rn and 226Rn by accelerating beams of these radioactive nuclei. We show that radon isotopes undergo octupole vibrations but do not possess static pear-shapes in their ground states. We conclude that radon atoms provide less favourable conditions for the enhancement of a measurable atomic electric-dipole moment.

1 Introduction

It is well established by the observation of rotational bands that atomic nuclei can assume quadrupole deformation with axial and reflection symmetry, usually with the shape of a rugby ball. The distortion arises from long-range correlations between valence nucleons which becomes favourable when the proton and/or neutron shells are partially filled. For certain values of proton and neutron number it is expected that additional correlations will cause the nucleus to also assume an octupole shape (`pear-shape') where it loses reflection symmetry in the intrinsic frame [1]. The fact that some nuclei can have pear shapes has influenced the choice of atoms having odd-A nuclei employed to search for permanent electric-dipole moments (EDMs). Any measurable moment will be amplified if the nucleus has octupole collectivity and further enhanced by static-octupole deformation. At present, experimental limits on EDMs, that would indicate charge-parity (CP) violation in fundamental processes where flavour is unchanged, have placed severe constraints on many extensions of the Standard Model. Recently, new candidate atomic species, such as radon and radium, have been proposed for EDM searches. For certain isotopes octupole effects are expected to enhance, by a factor 100-1000, the nuclear Schiff moment (the electric-dipole distribution weighted by radius squared) that induces the atomic EDM [2, 3, 4], thus improving the
parity of radon have been listed in the literature, for example moments [9-17]. For this reason, different isotopes of nuclei proposed as candidates for atomic EDM searches much less is known about the behaviour of radon (Rn) of experiments [11-13] is 223Rn. In contrast to the radium isotopes, isotope for theoretical calculations [9,10] and the planning produce radioactive ions. We observe that 224,226Rn require significant advances in the technology used to the astatine parent) is presently not possible, as it will be unattainable for theoretical calculations [9,10] and the planning of experiments [11-13] is 223Rn.

In this work [18] we present new data on the energy levels of heavy even-even Rn isotopes to determine whether parity doublets are likely to exist near the ground state of neighbouring odd-mass Rn nuclei. Direct observation of low-lying states in odd-\(A\) Rn nuclei (for example following Coulomb excitation or \(\beta\)-decay from the astatine parent) is presently not possible, as it will require significant advances in the technology used to produce radioactive ions. We observe that 224,226Rn behave as octupole vibrators in which the octupole phonon is aligned to the rotational axis. We conclude that there are no isotopes of radon that have static octupole deformation, so that any parity doublets in the odd-mass neighbours will not be closely spaced in energy. This means that radon atoms will provide less favourable conditions for the enhancement of a measurable atomic electric-dipole moment.

2 Results

2.1 Measurement of the quantum structure of heavy radon isotopes

In the experiments described here, 224Rn (\(Z = 86, N = 138\)) and 226Rn (\(Z = 86, N = 140\)) ions were produced by spallation in a thick thorium carbide target bombarded by \(\sim 10^{13}\) protons s\(^{-1}\) at 1.4 GeV from the CERN PS Booster. The ions were accelerated in HIE-ISOLDE to an energy of 5.08 MeV per nucleon and bombarded secondary targets of 120Sn. In order to verify the identification technique, another isotope of radon, 222Rn, was accelerated to 4.23 MeV/u. The \(\gamma\)-rays emitted following the excitation of the target and projectile nuclei were detected in Miniball [19], an array of 24 high-purity germanium detectors, each with six-fold segmentation and arranged in eight triple-clusters. The scattered projectiles and target recoils were detected in a highly segmented silicon detector [20].

Prior to the present work, nothing was known about the energies and spins of excited states in 224,226Rn, while de-exciting \(\gamma\)-rays from states in 222Rn had been observed [21] with certainty up to \(I^\pi = 13^-\). The chosen bombarding energies for 224,226Rn were about 3\% below the nominal Coulomb barrier energy at which the beam and target nuclei come close enough in head-on collisions for nuclear forces to significantly influence the reaction mechanism. For such close collisions the population of high-spin states will be enhanced, allowing the rotational behaviour of the nucleus to be elucidated. This is the method has been coined “unsafe Coulomb excitation” [22] as the interactions between the high-Z reaction partners is predominantly electromagnetic. It is not possible to precisely determine electromagnetic matrix elements because of the small nuclear contribution. The most intense excited states expected to be observed belong to the positive-parity rotational band, built upon the ground state. These states are connected by fast E2 transitions. In nuclei that are unstable to pear-shaped distortion, the other favoured excitation paths are to members of the octupole band, negative-parity states connected to the ground-state band by strong E3 transitions.

![Figure 1. Spectra of \(\gamma\)-rays.](image)

The \(\gamma\)-rays were emitted following the bombardment of 120Sn targets by 222Rn (black), 224Rn (blue), and 226Rn (red). The \(\gamma\)-rays were corrected for Doppler shift assuming that they are emitted from the scattered projectile. Random coincidences between Miniball and CD detectors have been subtracted. The transitions which give rise to the observed full-energy peaks are labelled by the spin and parity of the initial and final quantum states. The assignments of the transitions from the negative parity states in 224,226Rn are tentative (see text).
The spectra of γ-rays time-correlated with scattered beam and target recoils are shown in figure 1. The E2 γ-ray transitions within the ground-state positive-parity band can be clearly identified, as these de-excite via a regular sequence of strongly-excited states having spin and parity $0^+, 2^+, 4^+, \ldots$ with energies $\frac{k^2}{2J}(I + 1)$. In this expression the moment-of-inertia $\Sigma$ systematically increases with increasing $I$ (reducing pairing) and with number of valence nucleons (increasing quadrupole deformation). As expected from multi-step Coulomb excitation the intensities of the transitions systematically decrease with increasing $I$, after correcting for internal conversion and the γ-ray detection efficiency of the Miniball array.

The other relatively intense γ-rays observed in these spectra with energies < 600 keV are assumed to have E1 multipolarity, and to depopulate the odd-spin negative-parity members of the octupole band. In order to determine which states are connected by these transitions, pairs of coincident γ-rays were examined. In this analysis, the energy spectrum of γ-rays coincident with one particular transition is generated by requiring that the energy of this 'gating' transition lies in a specific range. Typical spectra obtained this way are shown in figure 2. Each spectrum corresponds to a particular gating transition, background-subtracted, so that the peaks observed in the spectrum arise from γ-ray transitions in coincidence with that transition.

![Figure 2. Coincidence γ-ray spectra. The representative background-subtracted γ-ray spectra are in time-coincidence with different gating transitions. Here the observed peaks are labelled by the energy (in keV) of the transition. The gating transition is additionally labelled by the proposed spin and parity of the initial and final states.](image)

The level schemes for $^{224,226}$Rn constructed from the coincidence spectra, together with the known [20] scheme for $^{222}$Ra, are shown in figure 3. For $^{228}$Rn energy of the strongly-converted $2^+ \rightarrow 0^+$ transition overlaps with those of the Kα X-rays, but its value can be determined assuming that the relative intensity of Kα, Kβ X-rays is the same as for $^{222,224}$Rn. The E2 transitions connecting the states in the octupole band are not observed because they cannot compete with faster, higher-energy E1 decays.

The only other plausible description for this band is that it has $K^\pi = 0^+ or 2^+$, implying that the $K^\pi = 0^-$-octupole band is not observed. This is unlikely as the bandhead would have to lie significantly lower in energy than has been observed in $^{222,224,225}$Ra, and inter-band transitions from states with $I' > 4$ to states with $I = 0$ in the ground-state band and in-band transitions to $I' = 2$ would all be visible in the spectra. The spin and parity assignments for the positive-parity band that is strongly populated by Coulomb excitation can be regarded as firm, whereas the negative-parity state assignments are made in accord with the systematic behaviour of nuclei in this mass region.

### 2.2 Characterisation of octupole instability

From the level schemes and from the systematics for all the radon isotopes (figure 4) it is clear that the bandhead of the octupole band reaches a minimum around $N=136$. The character of the octupole bands can be explored [23] by examining the difference in aligned angular momentum, $\Delta I = \bar{I}^x - \bar{I}^y$, at the same rotational frequency $\omega$, as a function of $\omega$. Here $\bar{I}^x$ is approximately $I$ for $K=0$ bands and $\hbar \omega$ is approximately $(E_i - E_{i-2})/2$.

For nuclei with permanent octupole deformation $\Delta I_x$ is expected to approach zero, as observed for several isotopes of Ra, Th, and U [5]. For octupole vibrational nuclei in which the negative-parity states arise from coupling an octupole phonon to the positive-parity states, it is expected that $\Delta I_x \sim 3\hbar$ as the phonon prefers to align with the rotational axis. This is the case for the isotopes $^{218,220,222,224}$Rn at values of $\hbar \omega (< 0.2$ MeV) where particle-hole excitations do not play a role, see figure 4.

Thus we have clearly delineated the lower boundary at $Z > 86$ as to where permanent octupole deformation occurs in nature.

### 3. Discussion

The observation of octupole-vibrational bands in the even-even radon isotopes is consistent with several theoretical calculations [24-26], which predict that only nuclei with $Z > 86$ have stable octupole deformation. Other calculations suggest that radon isotopes with $A = 222$ will have non-zero values of the octupole deformation parameter $\beta_3$[27-28]. For such nuclei which
have a minimum in the nuclear potential energy at non-zero values of $\beta_3$, the positive- and negative-parity states are projected from intrinsic configurations having $K = 0^+, 0^-$ which are degenerate in energy. In the odd-$A$ neighbours parity doublets arise by coupling the odd particle to these configurations.

Figure 4. Systematic behaviour of radon isotopes. (a) Systematics of the energies for different spins of low-lying positive-parity (black) and negative-parity states (red) in radon isotopes; (b) cartoon illustrating how the octupole phonon vector aligns with the rotation ($\mathbf{R}$) vector (which is orthogonal to the rotating body’s symmetry axis) so that $I = R + 3\hbar$ and $\Delta \mathbf{I} = 3\hbar$; (c) difference in aligned spin for negative- and positive-parity states in $^{218-222}$Rn (re-analysed for $^{218-222}$Rn that have been presented earlier [23]). The dashed line at $\Delta \mathbf{I} = 0$ is the expected value for static octupole deformation. This is not the case for reflection-symmetric nuclei that undergo octupole vibrations around $\beta_3 = 0$. Bands of opposite parity with differing single-particle configurations can lie close to each other fortuitously [29-30] but in general those arising from coupling the odd nucleon to the ground state and octupole phonon will be well separated. The separation will be determined by the spacing of the bands in the even-even core, ~500 keV in the case of $^{222-226}$Rn (see figure 4), and will be in general much larger than that the value (~50 keV) observed for parity doublets in radium isotopes [1]. Quantitative estimates of Schiff moments for octupole-vibrational systems have yet to be made [31-32]. Nevertheless, it can be concluded that, if measurable CP-violating effects occur in nuclei, the enhancement of nuclear Schiff moments arising from octupole effects in odd-$A$ radon nuclei is likely to be much smaller than for heavier octupole-deformed systems.

4. Outlook

We have also carried out measurements of $\gamma$-ray yields following the Coulomb excitation of $^{222}$Rn, $^{222,228}$Ra, at bombarding energies sufficiently below the Coulomb barrier to allow the extraction of multipole matrix elements using the GOSIA analysis technique [33]. Typical spectra are shown in figure 5. The analysis of these data is in progress; we expect to obtain $E_1$, $E_2$ and $E_3$ matrix elements for transitions between states in the low-lying collective band in these nuclei.

Figure 5. Spectra of $\gamma$-ray transitions in $^{222}$Ra (upper) and $^{228}$Ra (lower) following bombardment of $^{120}$Sn (blue) and $^{60}$Ni (red) targets. The $\gamma$-rays are corrected for Doppler shift assuming that they are emitted from the scattered projectile.

We are grateful to Niels Bidault, Eletherios Fadakis, Erwin Siesling, and Fredrick Wenander who assisted with the preparation of the radioactive beams, and we thank Jacek Dobaczewski for useful discussions. The support of the ISOLDE Collaboration and technical teams is acknowledged.
