42
43 44 **ABSTRACT**

44
45 45 Deimatic behaviours, also referred to as startle behaviours, are used against predators and

46
47 46 rivals. Although many are spectacular, their proximate and ultimate causes remain unclear. In

48
49 47 this review we aim to synthesise what is known about deimatic behaviour and identify

50
51 48 knowledge gaps. We propose a working hypothesis for deimatic behaviour, and discuss the

1
2
3 49 available evidence for the evolution, ontogeny, causation, and survival value of deimatic
4
5 50 behaviour using Tinbergen's Four Questions as a framework. Our overarching aim is to
6
7 51 direct future research by suggesting ways to address the most pressing questions in this field.

37
38 138 **I. INTRODUCTION**

39
40 139 Avoiding predation is essential for prey fitness. Defending against predators can be costly in
41
42 140 terms of time, energy, injury, and death. Therefore, traits that reduce these costs are
43
44 141 widespread and diverse. The variety of defensive traits includes: camouflage – concealing
45
46 142 colours and patterns (Endler, 1978; Stevens & Merilaita, 2011); aposematism – warning
47
48 143 colour patterns and sounds (Mappes, Marples & Endler, 2005); retaliation – expulsion of
49
50 144 blood, toxins, and hot fluids (Eisner, 1970; Sherbrooke, Middendorf & Guyer, 2001); armour
51
52 145 – defensive structures like spines and hard integuments (Speed & Ruxton, 2005); and
53
54 146 mimicry in many forms (Skelhorn *et al.*, 2010; Dell’Aglia *et al.*, 2018). How defensive traits
55
56 147 such as visual warning signals work against predators is well understood (Mappes *et al.*,
57
58
59
60

1
2
3 148 2005), while others like deimatic behaviours (Fig. 1), remain poorly understood. Cott (1940,
4
5 149 p. 213) commented on deimatic behaviour stating “*Indeed, we have here an almost untrodden*
6
7 150 *field for future research*”. More than 80 years later this statement remains true save for a
8
9 151 surge of research in the 1970s, and a more recent second wave. The recent resurgence has
10
11 152 precipitated this collaborative review in which we: (1) suggest a hypothesis for deimatism as
12
13 153 distinct from other defences; (2) critically evaluate examples of deimatism and their
14
15 154 classification; and (3) apply Tinbergen’s ‘Four Questions’ framework (Tinbergen, 1963) on
16
17 155 evolution, ontogeny, causation, and survival value, to synthesise the literature and identify
18
19 156 the critical knowledge gaps we need to fill to understand the evolution of deimatism.

25

26 158 **II. WHAT IS DEIMATIC BEHAVIOUR?**

27
28 159 Deimatic behaviour [*sensu* Maldonado (1970) and Edmunds (1974)] is a celebrated ‘textbook
29
30 160 example’ of a spectacular antipredator defence (Fig. 1), but what exactly is it? Despite long-
31
32 161 standing scientific interest (see online Supporting Information, Table S1) no strong consensus
33
34 162 has so far emerged, nor has a name even been settled on although more than a dozen have
35
36 163 been proposed, with ‘deimatic behaviour’ and ‘startle display’ persisting into the modern
37
38 164 literature (Table S1).
39
40
41

42 165 The first occurrence of the phrase ‘startle display’ in the animal behaviour literature
43
44 166 seems to be in Crane’s (1952) work on Trinidadian mantises, described as the “*type of*
45
46 167 *behavior in which tegmina and wings are elevated and special associated motions made in*
47
48 168 *the face of a potential threat. The more usual terms ‘frightening’ or ‘intimidating display’*
49
50 169 *seem too strong to apply in most of the current instances*” (p. 261). Since Crane (1952), the
51
52 170 term ‘startle’ has been used to describe the prey’s behaviour without knowledge of whether
53
54 171 in fact the behaviour releases the startle reflex in the attacker (Skelhorn, Holmes & Rowe,
55
56 172 2016). Maldonado (1970) coined the phrase ‘deimatic behaviour’. ‘Deimatic’ is from the
57
58
59
60

1
2
3 173 Greek for ‘frighten’ (Liddell *et al.*, 1996) which we note is the same root as Deimos the
4
5 174 Greek God of Terror (Grant & Hazel, 2004). Maldonado (1970) defined deimatic behaviour
6
7
8 175 in prey as “*a conspicuous display when they are faced with a ‘threat’*” (p. 61). Edmunds
9
10 176 (1974) expanded Maldonado’s definition and described ‘deimatic behaviour’ in a range of
11
12 177 species and stipulated that it “*stimulates an attacking predator to withdraw and move away.*
13
14
15 178 *This results in a period of indecision on the part of the predator... and this gives the*
16
17 179 *displaying animal an increased chance of escaping*” (p. 150). To avoid assumptions about
18
19 180 mechanisms and form, we suggest the use of ‘deimatic behaviour’ instead of ‘startle display’.
20
21 181 We suggest avoiding the term ‘startle’ because it is not yet clear by how many or which
22
23 182 mechanisms deimatic behaviour can be protective (see Section II.7) and we suggest avoiding
24
25 183 the word ‘display’ because it can imply visual signals and exclude other sensory modalities
26
27 184 (Edmunds, 1974; Ruxton, Sherratt & Speed, 2004).

30
31 185 Descriptions of deimatic behaviours are inconsistent across the literature. They have
32
33 186 been described as behaviours performed by prey as a predator approaches, that cause
34
35 187 predators to hesitate long enough for prey to escape. However, many species – including
36
37 188 most of those described in the literature – perform their deimatic behaviour during
38
39 189 subjugation, long after approach (Table S1). Deimatic behaviours are often described as a
40
41 190 ‘bluff’ (Ruxton *et al.*, 2004) which assumes that besides the display, prey pose no further
42
43 191 threat. That is, it assumes that prey lack a chemical or physical defence, and disregards any
44
45 192 protective value of the performance itself. Also, species have been described as deimatic in
46
47 193 ways that imply that their whole antipredator strategy is ‘deimatic’ (Umbers & Mappes,
48
49 194 2015). All of the above approaches have proved problematic when then trying to place
50
51 195 deimatism in context with other defences (Skelhorn *et al.*, 2016). We therefore suggest that
52
53 196 antipredator strategies can include many ‘defences’ such as crypsis, masquerade, and
54
55 197 aposematism; any one of which may be a deimatic behaviour (Umbers *et al.*, 2017) (Fig. 2).
56
57
58
59
60

1
2
3 198 Given the overall lack of clarity, but considering the main conceptual points from previous
4
5 199 contributions to the field, we suggest the following hypothesis for what constitutes deimatic
6
7 200 behaviour: *a behaviour performed by a target different from fleeing and retaliation that is*
8
9 201 *triggered by it perceiving threat from an attacker during approach or subjugation, and which*
10
11 202 *can trigger an unlearned avoidance response in the attacker causing it to slow or stop its*
12
13 203 *attack.*
14
15

16
17 204 There are four key components of our hypothesis and we provide rationales for each below
18
19 205 plus a summary of our deliberate exclusions.
20
21

22 206

23
24 207 **(1) Component 1: “A behaviour performed by a target different from fleeing and**
25
26 208 **retaliation...”**

27
28 209 “Behaviour” here is to be interpreted very broadly as something an organism can do
29
30 210 including body part movements, the emission of sounds or chemicals, or dynamic changes in
31
32 211 colour patterns. The inclusion of the word “performed” is intended to emphasise that it is a
33
34 212 discrete state that the prey adopts for a time and to distinguish it from more continuous states,
35
36 213 such as constantly exposed aposematic colouration. The behaviour may have been selected to
37
38 214 induce the attacker’s response or the attacker’s response may be an accidental by-product of a
39
40 215 prey behaviour.
41
42

43
44 216 A “target” is the organism or group of organisms that is being attacked, including
45
46 217 colonies and other diffuse phenotypes. The target may not always be prey and could be a
47
48 218 competitor (Edmunds, 1974). Deimatic behaviours do not involve the target fleeing from an
49
50 219 attack. They *can* be performed while fleeing, but their protective value is not in avoiding
51
52 220 capture by increasing physical distance. Deimatic behaviours do not include retaliation (*sensu*
53
54 221 Edmunds, 1974), in which predators can be physically harmed such as by toxic sprays
55
56 222 (Eisner, 1970).
57
58
59
60

223

224 **(2) Component 2: “...triggered by it perceiving threat from an attacker during**
225 **approach or subjugation...”**

226 The implication here is that deimatic behaviour evolves in response to attack, and the form
227 has been influenced by the effect that it has on an attacker, so it is a signal not a cue
228 (Maynard Smith & Harper, 2003). It is triggered by the target perceiving, rightly or wrongly,
229 that it is threatened; it requires the target to detect the attack. With “perceiving” we intend to
230 include the most neurologically simple stimulus–response processes. We predict the
231 behaviour will only be performed outside of a threatening context by mistake, for example
232 when targets misidentify an event as a threat (akin to false alarm). We also predict the
233 behaviour will typically be performed for brief time intervals, or at least not very long
234 beyond the period of interaction with an attacker. While “attacker” often refers to a predator
235 or competitor, it also extends to the range of natural enemies such as parasitoids, parasites,
236 and micropredators (*sensu* Lafferty & Kuris, 2002). Display initiation should coincide with
237 the physical proximity of an attacker within some relevant distance – we suggest the phrase
238 ‘display initiation distance’ (*sensu* Aguilar-Argüello, Díaz-Fleischer & Rao, 2016) – and it
239 will cease upon the perceived threat passing, such as when the attacker leaves the scene or
240 obviously changes its motivation (e.g. from a focused attack to ignoring, or if the prey
241 escapes the predator). The onset of deimatic behaviour may be sudden if it is the result of a
242 threat threshold being breached, but we suggest leaving the time taken to begin performing
243 the display open because slow transitions may be as effective as fast ones (Holmes *et al.*,
244 2018). Deimatic behaviours are performed during predator approach or subjugation – they
245 may function to prevent consumption.

246

1
2
3 247 **(3) Component 3: "...which can trigger an unlearned avoidance response in the**
4
5 248 **attacker ..."**

6
7 249 We predict that deimatic behaviour can impact the attacker through a change in their
8
9 250 perception of their target in any sensory mode. The change does not have to result from
10
11 251 learning or prior experience. The attacker's response could involve cognition and/or could be
12
13 252 affected by reflexive responses. We also predict that the attacker's response may change in
14
15 253 response to sensory adaptation, habituation, confusion, motor fatigue, state of arousal, and, of
16
17 254 course, associative learning, perhaps related to withdrawing from a threat. The implication of
18
19 255 "can" is that the target's behaviour will occur often enough for the behaviour to be favoured
20
21
22
23
24 256 by selection.

25
26 257

27
28 258 **(4) Component 4: "...causing it to slow or stop its attack."**

29
30 259 Our hypothesis requires that deimatic behaviour causes the attacker to slow or stop its attack.
31
32 260 Guilford's (1994) 'go-slow' hypothesis suggests that predators may be more cautious when
33
34 261 faced with an aposematic signal, we predict the same may be true for deimatic behaviours.
35
36 262 The attacker may continue to attack after responding to deimatic behaviour; this still counts
37
38 263 as deimatic. Although displays may not always be effective, the likelihood of survival should
39
40 264 be higher for individuals that choose to perform the behaviour compared to those that do not;
41
42 265 at least in some circumstances. Any slowing or termination of attack will be adaptive to the
43
44 266 prey.

45
46
47
48
49 267

50
51 268 **(5) Deliberate exclusions from the hypothesis**

52
53 269 Our hypothesis deliberately excludes certain words and phrases to remain inclusive of several
54
55 270 concepts. We have avoided the terms predator and prey because although deimatic displays
56
57 271 are commonly thought of in predator-prey interactions, they also occur in other contexts such
58
59
60

1
2
3 272 as intraspecific interactions (Edmunds, 1974). We expressly avoid specifying the mechanism
4
5 273 underlying the attacker's response, as several could be exploited. Our hypothesis allows the
6
7 274 target to be 'defended' or 'undefended' because the presence and strength of defences beyond
8
9
10 275 the behaviour are not needed for it to be deimatic and, equally, their presence does not
11
12 276 preclude deimatism (Fig. 2). The definition also deliberately does not specify the target's
13
14 277 behavioural state at the end of the display which could include the target returning to its
15
16
17 278 previous state, or fleeing (de-escalation) or retaliation (escalation) (Edmunds, 1972).
18
19 279

20 21 280 **(6) Deimatism as a distinct defence**

22
23
24 281 The biggest challenge in articulating the concept of deimatic behaviour is in determining the
25
26 282 conceptual boundaries between it and other antipredator defences. Here we discuss the
27
28 283 conceptual similarities and differences among deimatism and other defences. For clarity, we
29
30 284 use the phrase 'antipredator strategy' to mean the combination of defences an animal uses
31
32
33 285 such as crypsis, masquerade, aposematism, deimatism, and/or types of mimicry, each of
34
35 286 which may be encountered by predators or deployed by prey at different stages of the
36
37
38 287 predation sequence (Fig. 2) and may be multimodal and/or multicomponent (Rowe &
39
40 288 Guilford, 1999). We expand the primary/secondary defences dichotomy to recognise that an
41
42 289 antipredator strategy can be a sequence of any length – primary, secondary, tertiary,
43
44 290 quaternary, quinary, etc. (Endler, 1986, 1991) (Fig. 2).

45
46
47 291 Where does deimatism fit among other antipredator defences? The concepts of most
48
49 292 antipredator defences are not crystal clear, with many different definitions presented and the
50
51 293 distinctions between defences muddy. In addition, relative to other defences like
52
53 294 aposematism and camouflage, the mechanisms and functions of deimatism are not well
54
55
56 295 understood. This makes the necessary task of explaining clear conceptual distinctions
57
58 296 difficult, particularly compared to flash behaviour, retaliation, and aposematism.
59
60

1
2
3 297 Deimatic behaviour can resemble, although is functionally distinct from, fleeing
4
5 298 responses like ‘flash behaviours’ (*sensu* Edmunds, 1974) which often take the form of
6
7
8 299 repeatedly revealed colour patches and/or sounds by escaping prey (Table S2). These signals
9
10 300 are thought to impair the ability of attackers to track a fleeing signaller (Loeffler-Henry *et al.*,
11
12 301 2018) whereas deimatic behaviours are not protective *via* disrupting prey tracking or
13
14 302 increasing the distance between predator and prey (Edmunds, 1974; Loeffler-Henry *et al.*,
15
16 303 2018). Aspects of deimatic behaviour also overlap with retaliatory defences (*sensu* Edmunds,
17
18 304 1974) such as the defensive sprays of bombardier beetles. Such behaviours are also
19
20 305 performed when under threat, but differ in that predators are attacked rather than just
21
22 306 displayed to.
23
24

25
26 307 Debate and confusion has surrounded whether deimatism is distinct from
27
28 308 aposematism (Skelhorn *et al.*, 2016; Umbers & Mappes, 2016). In their most general sense,
29
30 309 aposematic signals can be loosely defined as ‘go away’ signals to predators. Such a broad
31
32 310 definition can include many concepts currently considered distinct: warning colouration,
33
34 311 flash colouration, types of mimicry and deimatism. This could mean that deimatism is a type
35
36 312 of aposematism, in the same way that crypsis and masquerade are both types of camouflage
37
38 313 (Skelhorn *et al.*, 2010). But if the term aposematism is used as an umbrella term for all those
39
40 314 concepts, classic warning signals need to be given a new name, which could cause
41
42 315 unnecessary confusion.
43
44

45
46 316 A more useful and biologically precise definition states that aposematism is “...*the*
47
48 317 *association between the signal and unprofitability...*”, that “*Aposematic signals work best*
49
50 318 *when they are easily detectable and memorable, which facilitates avoidance learning...*”, and
51
52 319 that the benefits of aposematism “...*increase as a function of the density of the similarly*
53
54 320 *signalling individuals...*” (Mappes *et al.*, 2005, p. 598). Deimatism does not fit this definition
55
56 321 well. There is preliminary evidence that deimatic behaviours are more effective against naïve
57
58
59
60

1
2
3 322 predators than experienced ones, which is opposite to the expectations of signals that
4
5 323 facilitate avoidance learning (Umbers *et al.*, 2019). Deimatic behaviours are not easily
6
7 324 detectable; they are temporary and undetectable until they are performed. Learning is not
8
9 325 necessary for deimatism to afford protection, which is a major difference from aposematism
10
11 326 *via* learned aversion, although learning might be associated with deimatism after the first
12
13 327 encounter (Kang *et al.*, 2016). It is currently unclear whether deimatic behaviours facilitate or
14
15 328 impede memorability, and both are possible (Kang *et al.*, 2016). Finally, the benefits of
16
17 329 deimatic behaviour can in theory decrease as a function of density, rather than increase, as
18
19 330 attackers learn to expect the performance (Sargent, 1990; Ingalls, 1993).

20
21
22 331 Deimatic behaviours can, however, be part of an antipredator strategy that includes an
23
24 332 aposematic signal (Umbers *et al.*, 2017) (Fig. 2). If an antipredator strategy includes
25
26 333 deimatism and aposematism, deimatic behaviour may cause a predator to break off its attack
27
28 334 before directly experiencing any of the prey's other defences. The deimatic function may
29
30 335 then hamper development of avoidance learning and reduce the efficacy of, or requirement
31
32 336 for, aposematism. Antipredatory strategies that include deimatism can also include Batesian
33
34 337 mimicry (for example through revealing markings that mimic a dangerous predator), the use
35
36 338 of eyespot signals, or retaliation, and equally, deimatic behaviour can be followed by no
37
38 339 further defence (Fig. 2).

39
40
41
42
43
44
45 340

46 341 **(7) Mechanisms by which predators respond to initial encounters with deimatic** 47 48 342 **behaviour**

49
50
51 343 The sensory and cognitive mechanisms deimatic behaviours exploit in predators are currently
52
53 344 unclear. Several non-mutually exclusive hypotheses have been suggested: release of the
54
55 345 startle reflex, the looming reflex, the release of fear in the predator, sensory overload,

1
2
3 346 confusion, and neophobia. Experimentally distinguishing among these mechanisms is an
4
5 347 important challenge to meet.
6
7
8 348

9
10 349 *(a) Startle reflex*

11
12 350 Deimatic behaviours are often colloquially referred to as ‘startle displays’, in that when
13
14 351 predators encounter them they appear to be startled (Crane, 1952; Schlenoff, 1985). But this
15
16 352 description is largely anthropomorphic and requires biological specificity. Vaughan (1983)
17
18 353 tested the responses of blue jays (*Cyanocitta cristata*) to artificial prey in which ‘startle
19
20 354 response’ was defined as “*a measurable hesitation in the normal feeding sequence of a*
21
22 355 *predator*” (Vaughan, 1983, p. 385). Further measures of ‘startle’ have included response
23
24 356 variables of mixed specificity: increased heart rate, latency to reinvestigate, hesitating,
25
26 357 jumping back, diving away, fleeing, contraction of facial and skeletal muscles, jumping,
27
28 358 rearing, running, grinding teeth, and quivering (Burnham, 1939; Bura *et al.*, 2011; Ramirez-
29
30 359 Moreno & Sejnowski, 2012; Fischer, Franco & Romero, 2016; Holmes *et al.*, 2018). These
31
32 360 behaviours and physiological responses could occur for several reasons and not necessarily as
33
34 361 a result of eliciting a startle reflex as defined in its strictest sense.
35
36
37
38
39

40 362 The ‘startle reflex’ is a response that interrupts what an animal is currently doing and
41
42 363 produces physiological and behavioural changes that help it evade an immediate threat
43
44 364 (Eaton, Bombardieri & Meyer, 1977; Gotz & Janik, 2011; Yilmaz & Meister, 2013; Skelhorn
45
46 365 *et al.*, 2016). The startle reflex appears to be triggered by stimuli, whether auditory or visual,
47
48 366 that have a high intensity and a rapid onset (Koch & Schnitzler, 1997; Koch, 1999; Deuter *et*
49
50 367 *al.*, 2012). For example, in laboratory experiments where sounds are produced in close
51
52 368 proximity to subjects (usually primates and rodents), sounds typically need to be above 80–
53
54 369 90 dB with rapid rise times (the time taken for the stimulus to reach its maximum amplitude)
55
56 370 of less than 12 ms (Davis, 1984), but sounds of 60 dB can also be effective if they have close
57
58
59
60

1
2
3 371 to instantaneous rise times (Åsli & Flaten, 2012). Caterpillars that make sounds in response
4
5 372 to attack can produce them close to instantaneously at 70–90 dB when the predator is at close
6
7
8 373 range, but the limited data available suggest that deimatic behaviours rarely have such intense
9
10 374 and rapid onset, at least for auditory signals. Therefore, although the startle reflex is
11
12 375 taxonomically widespread, and exploiting it could protect against many enemies, it is
13
14 376 unlikely to be the mechanism by which all deimatic behaviours protect.
15
16

17 377

18
19 378 *(b) Looming reflex*

20
21 379 Deimatic displays may trigger the ‘looming reflex’, an adaptive response to avoid rapidly
22
23 380 approaching objects, including predators (Yamawaki, 2011). The looming reflex has been
24
25
26 381 studied across a wide range of species including insects (Rind, Santer & Wright, 2008;
27
28 382 Yamawaki, 2011), crustaceans (Shragai *et al.*, 2017), cephalopods (King & Adamo, 2006;
29
30 383 Hanlon & Messenger, 2018) and chordates (Temizer *et al.*, 2015), and is characterised by
31
32 384 receivers taking rapid evasive action to avoid contact with the approaching object. Like
33
34 385 startle reflexes, the stimuli that induce this response are specific – looming-sensitive neurons
35
36 386 respond to stimuli that increase rapidly in surface area on the retina (Yilmaz & Meister,
37
38 387 2013). For example, mice respond to rapidly looming discs, but only when they come from
39
40 388 above at speeds that resemble an incoming aerial predator (Yilmaz & Meister, 2013). Some
41
42 389 deimatic behaviours involve a rapid increase in size (Table S3) and although it is not known
43
44 390 if such changes are sufficient in size or speed, it is possible they evoke the looming response.
45
46 391 To take advantage of predator looming reflexes we predict that deimatic behaviour may have
47
48 392 the greatest survival value when it appears to make the apparent size of the prey increase
49
50 393 rapidly, and perhaps at close range so that they can stimulate a larger area of the predator’s
51
52 394 retina.
53
54
55
56
57
58
59
60

1
2
3 396 (c) *Fear responses*
4

5 397 Responses to deimatic behaviour seem to occur very quickly (i.e. reflex-like), and may use
6
7 398 specific neural systems that do not involve time-consuming identification of the approaching
8
9 399 stimulus in order to enable rapid life-saving responses (Lin, Murray & Boynton, 2009).
10
11 400 However, another hypothesis for how deimatic behaviours work is that they elicit fear
12
13 401 responses because a stimulus is recognised and misclassified as a potential threat (Skelhorn *et*
14
15 402 *al.*, 2016). Phasic fear is a state of apprehension elicited by a specific and imminent perceived
16
17 403 threat, that dissipates once the danger is removed (Davis *et al.*, 2010; Miles, Davis & Walker,
18
19 404 2011; Sato & Yamawaki, 2014; Tovote *et al.*, 2016). It produces responses that can be rapid,
20
21 405 occurring within 100 ms of stimulus onset, and could mediate observers' responses to
22
23 406 deimatic behaviour (Pomeroy & Heppner, 1977; Åsli & Flaten, 2012). The kinds of stimuli
24
25 407 perceived as threatening can be influenced by an animal's evolutionary history (Blumstein,
26
27 408 2006) or ontogeny, or by what it has learned from its own experiences or observations
28
29 409 (Griffin, 2004). This means that features of dangerous stimuli in a predator's environment
30
31 410 that are likely to elicit phasic fear responses could be exploited by deimatic behaviour. For
32
33 411 example, deimatic behaviour could include the revealing of eyespots that resemble sympatric
34
35 412 predatory eyes (Janzen, Hallwachs & Burns, 2010; De Bona *et al.*, 2015), or auditory signals
36
37 413 that sound like sympatric (or at least historically so) predatory alarm calls (Dookie *et al.*,
38
39 414 2017).
40
41
42
43
44
45
46
47
48

49 416 (d) *Sensory overload*

50
51 417 Deimatic behaviours could somehow overwhelm a predator's ability to process sensory
52
53 418 information by presenting them with more information or noise than they can process at once
54
55 419 (Hebets & Papaj, 2004; Low, 2012). This popular idea has been referred to as 'sensory
56
57 420 overload' (Hebets & Papaj, 2004; Bro-Jørgensen, 2010). However, this term is often used
58
59
60

1
2
3 421 loosely, and clear conceptual definitions are rare (Scheydt *et al.*, 2017), particularly in the
4
5 422 animal signalling literature. From a mechanistic point of view, the behavioural phenomena
6
7 423 that appear to be associated with sensory overload (e.g. behavioural immobilization and
8
9 424 confusion) may be caused when excessive stimulation from at least two sensory modes
10
11 425 blocks the reticular formation; a complex network of brainstem nuclei involved in (amongst
12
13 426 other things) perception, attention and maintaining behavioural arousal (Lindsley, 2013).
14
15 427 Related concepts probably include visual or auditory distraction, sensory filtering, cognitive
16
17 428 overload (Dukas & Kamil, 2000) and breakdown of multimodal/sensory integration.
18
19
20
21

22 429 Understanding the mechanisms by which deimatic behaviours protect prey from
23
24 430 predators requires directly measuring what the predator is experiencing, which may demand
25
26 431 more technically difficult and invasive data collection (Fullard, Dawson & Jacobs, 2003) than
27
28 432 measuring predator behaviour and carries important ethical considerations. The difficulty of
29
30 433 determining the mechanisms involved increases substantially when attempted in field
31
32 434 conditions (Skelhorn *et al.*, 2016; Umbers & Mappes, 2016). Both are worthy goals if we are
33
34 435 to understand how deimatic behaviours provide survival value.
35
36
37
38
39

40 437 *(e) Confusion effect*

41
42 438 As stated above, deimatic behaviour often involves the exposure of a previously hidden
43
44 439 signal that functions to startle a would-be attacker. However, the deployment of hidden
45
46 440 signals may also prevent attacks through other mechanisms. Specifically, a cryptic organism
47
48 441 revealing a conspicuous signal as it flees may confuse the attacker as to the organism's
49
50 442 appearance when at rest, hindering subsequent search. This defensive strategy is known as
51
52 443 'flash behaviour' and appears to be widespread in nature with putative examples having been
53
54 444 described in cephalopods, insects, fish, amphibians, reptiles, birds, and mammals (Edmunds
55
56 445 1974; Hanlon & Messenger, 2018). It has been postulated that the confusion effect of flash
57
58
59
60

1
2
3 446 behaviour may function in tandem with a startle effect to dissuade attackers (Edmunds, 1974;
4
5 447 Cott, 1940). However, a ‘proof of concept’ experiment demonstrated that the confusion effect
6
7 448 of flash behaviour alone is sufficient to prevent attacks (Loeffler-Henry *et al.*, 2018).
8
9
10 449 Moreover, flash displays may be more effective in reducing predation when the signaller
11
12 450 flees from a distance, so that the signaller’s cryptic resting state is not observed (Loeffler-
13
14 451 Henry, Kang & Sherratt, 2021). Since hidden signals are less likely to frighten the observer
15
16 452 when exposed from a distance, then deimatic and flash displays are functionally distinct and
17
18 453 may often be incompatible.
19
20
21
22
23

24 455 **III. DEIMATIC BEHAVIOUR ACROSS TAXA**

25
26 456 We collated all studies on deimatic behaviour and its analogues from the primary literature.
27
28 457 We include studies on deimatic and related phenomena based on descriptions in the literature
29
30 458 by the authors and as such may have included behaviours eventually deemed not to fit
31
32 459 deimatism and may have excluded deimatic behaviours that will be included in the future.
33
34 460 With those limitations, here we synthesise the literature on deimatic behaviour and discuss
35
36 461 the marginal cases.
37
38
39
40
41

42 463 **(1) Literature search methods**

43
44 464 We searched titles, abstracts, and key words in the *Web of Science* database, with relevant
45
46 465 terms gathered from Edmunds (1974), proposed definitions and iteratively, based on
47
48 466 preliminary descriptions we found in the literature (Table S1). Our search terms in the Title
49
50 467 [TI] field were: deimatic display OR deimatic response OR frightening attitude OR startl*
51
52 468 display OR defensive display OR startle behaviour OR deimatic behaviour OR startl* sound
53
54 469 OR startl* colour* OR startl* response OR startl* reaction OR dymantic display. This search
55
56 470 returned 1535 hits in February 2021. In addition, we searched for papers using the taxon-
57
58
59
60

1
2
3 471 specific terms: ‘unken reflex’ (amphibians), ‘hooding’ (cobras) and ‘disturbance stridulation’
4
5 472 (insects).
6
7
8 473

9
10 474 **(2) Results from literature search**

11
12 475 75 publications met at least one of two inclusion criteria: describing the form of putative
13
14 476 deimatic behaviour or describing a manipulative experiment on an aspect of deimatic
15
16 477 behaviour (Table S3). In total our data set included 224 species from 246 separate studies
17
18 478 within 75 publications (with ‘studies’ defined as descriptions or experiments within a
19
20 479 publication) with 16 species represented multiple times (Table S3) . Because so few species
21
22 480 have been studied multiple times, the number of studies is roughly representative of the
23
24 481 number of species, for a summary of the number of species see Fig. 3. Most studies were
25
26 482 descriptive accounts of putative deimatic behaviour ($N = 198/246$, 80%) rather than
27
28 483 manipulative experiments ($N = 48/246$, 20%), providing an important natural history base
29
30 484 from which to work but little evidence on the mechanistic and functional drivers of deimatic
31
32 485 behaviour. In the following sections we report trends from descriptive accounts. The results
33
34 486 from manipulative experiments are discussed in later sections.
35
36
37
38
39

40 487
41
42 488 *(a) History of describing deimatic behaviour*

43
44 489 Deimatic behaviour is no doubt known by indigenous people the world over, but to the
45
46 490 detriment of this review we found no modern indigenous accounts. However, we found some
47
48 491 evidence of ancient knowledge on snakes with putative deimatic behaviours in images and
49
50 492 written accounts. A rattlesnake’s rattle is prominently depicted in a pictograph dated to
51
52 493 approximately 1000 CE at the Pony Hills archaeological site, New Mexico (Schollmeyer,
53
54 494 2020). The Brooklyn Medical Papyrus dated 450 BCE, describes the hooding behaviour of
55
56 495 the Egyptian cobra (*Naja haja*), scale stridulation of saw-scaled vipers (*Echis* sp.), and
57
58
59
60

1
2
3 496 sounds of puff adders (*Bitis arietanis*) (Golding, 2020). The earliest written description of
4
5 497 deimatic behaviour in the scientific literature we could find is that of Goureau (1841) about
6
7 498 *Mantis religiosa* which roughly translates from French to: “*she raised her long corselet*
8
9 499 *vertically, carried her forelegs forward, as if to catch her prey, half spread her wings and*
10
11 500 *elytra, and moved her abdomen up and down with a rapid movement; during this movement,*
12
13 501 *the sides of the belly rubbed against the inner edges of the wings and elytra, and produced a*
14
15 502 *noise analogous to that obtained by crumpling parchment*” (Goureau, 1841, p. 354). Löhner
16
17 503 (1919) described the unken reflex (arched-back posture) in *Bombinator igneus* toads as
18
19 504 potentially hypnotising. Varley (1939) published a comprehensive summation of the
20
21 505 literature on mantis ‘frightening attitudes’ citing 29 publications including Roonwal’s (1938)
22
23 506 account of the ‘frightening display’ of the mantis *Eremiaphila braueri*. After a three-year
24
25 507 residence in the jungles of Trinidad, Crane (1952) published her comparative account of the
26
27 508 ‘defensive behaviour’ of 15 Trinidad mantis species. Blest (1957a) published a detailed
28
29 509 account of ‘protective displays’ in some Saturnioidea and Sphingidae Lepidoptera.
30
31 510 Throughout the 1970s there was a flourish of work on deimatic behaviour. Maldonado
32
33 511 described details of the form, habituation and ontogeny of deimatic behaviour in the double
34
35 512 eye-spot mantis (*Stagmatoptera biocellata*) (Maldonado, 1970; Balderrama & Maldonado,
36
37 513 1971, 1973).

38
39 514 In the early and mid 1970s, Edmunds published two extensive descriptions of the
40
41 515 ‘defensive behaviour’ of dozens of African mantises (Edmunds, 1972, 1976) and his
42
43 516 influential book *Defence in Animals: A Survey of Anti-predator Defences* (Edmunds, 1974),
44
45 517 in which he describes ‘deimatic behaviour’ across species and contexts. Also in the 1970s,
46
47 518 Brodie Jr led a series of publications that described the ‘defensive posturing’ of the newt
48
49 519 *Taricha granulosa* and dozens of salamander species (Johnson & Brodie Jr, 1975; Nowak &
50
51 520 Brodie, 1978). Since then, the field has progressed steadily including seminal works on the
52
53
54
55
56
57
58
59
60

1
2
3 521 underwing moths (*Catocala* spp.) in the 1980s and 1990s (Schlenoff, 1985; Sargent, 1990;
4
5 522 Ingalls, 1993) and peacock butterflies (*Aglais io*) in the 2000s (Vallin *et al.*, 2005; Olofsson,
6
7 523 Jakobsson & Wiklund, 2012b).

9
10 524

11
12 525 *(b) Taxonomic coverage, descriptions, predators and life stages*

13
14 526 The majority of studies describe the deimatic behaviour of salamanders (Urodela), moths and
15
16 527 butterflies (Lepidoptera), mantises (Mantodea), and frogs (Anura) (Table S3, Fig. 3) but this
17
18 528 is likely to be a poor summary because the concept and the kinds of behaviours included has
19
20 529 not been clear or applied consistently. Deimatic behaviour of 16 species has been described
21
22 530 multiple times, for example the European cuttlefish (*Sepia officinalis*), peacock butterfly, and
23
24 531 promethea silkworm (*Callosamia promethia*) (Table S3). Words most often used in the
25
26 532 descriptions are shown in Fig. 3E. Most studies focused on displays of adults (around 80%),
27
28 533 with just a handful of studies on juveniles (Table S3). A few studies covered both adult and
29
30 534 juvenile life stages and around 10% provided no information about life stage (Table S3). The
31
32 535 vast majority of studies used humans as predators with birds and non-human mammals a
33
34 536 distant second and third (Table S3, Fig. 3D).

35
36
37
38
39
40 537

41
42 538 *(c) Primary defence associated with deimatic behaviour and stage of predation sequence*

43
44 539 *deployed*

45
46 540 For most species, deimatic behaviour was associated with a form of camouflage (Fig. 3C) as
47
48 541 its primary defence. Exceptions were the salamanders which were considered aposematic
49
50 542 except for two *Pseudotriton* Batesian mimics, and the Io moths (*Automeris* spp.) which were
51
52 543 deemed putatively aposematic in the literature. Work on the co-evolution of primary
53
54 544 defences, deimatic behaviour, and further defences is key to understanding how different
55
56 545 defences interact to protect prey.

1
2
3 546
4
5
6 547*(d) Multimodality of deimatic behaviour*

7
8 548 About half the studies suggested that deimatic behaviours target more than one sensory mode
9
10 549 (Higham & Hebets, 2013) (Table S3). However, most studies focused on behaviours
11
12 550 involving movement of large body parts (the wings, body, tail, or head; Table S3, Fig. 3E).
13
14 551 Several visual components were reported: movement and body size increase, colour pattern
15
16 552 reveal including eyespots, light production (e.g. bioluminescence), and the revealing or
17
18 553 highlighting of a weapon. Most studies (~ 65%) involved visual components in addition to
19
20 554 movement. We found a few cases of putative Batesian mimicry where posturing alone was
21
22 555 thought to be protective. For example, the stick insect (*Oncotophasma martini*) curves its
23
24 556 abdomen over giving it the appearance of a scorpion (Robinson, 1968*b*), while the lobster
25
26 557 moth (*Stauropus fagi*) caterpillar adopts a spider-like posture (Poulton, 1890). The most
27
28 558 common incorporation of Batesian mimicry was in the reveal of eyespots [18 Lepidoptera
29
30 559 (especially Saturniidae: *Automeris*), two manitises, one cuttlefish and one frog]. Only about
31
32 560 one quarter of the studies included a focus on auditory, vibrational or olfactory components
33
34 561 and around 40% reported a gustatory or olfactory component (Table S3). It is unclear
35
36 562 whether visual components are more commonly associated with deimatic behaviour or just
37
38 563 more often studied (Rowe & Halpin, 2013).
39
40
41
42
43
44
45
46

564

(e) Speed and duration of deimatic behaviour

47 565
48
49 566 The movement involved in deimatic behaviour may be important for its protective value
50
51 567 (Holmes *et al.*, 2018) but speed and duration were rarely measured. We found no clear
52
53 568 information on the speed of state change (rise time) between resting and deimatic behaviours.
54
55 569 One exception was for the common octopus (*Octopus vulgaris*), which initiated changes to its
56
57 570 visual appearance in 270 ms and completed a dramatic colour pattern and skin texture change
58
59
60

1
2
3 571 in 2 s using its capacity for rapid neural polyphenism (Hanlon, 2007; Hanlon & Messenger,
4
5 572 2018). The European cuttlefish initiates dramatic changes in appearance over a similar time
6
7 573 frame, and varied these responses across three different species of teleost fish predators
8
9 574 (Staudinger, Hanlon & Juanes, 2011). In other taxa, display duration varied enormously
10
11 575 among species from milliseconds to more than 30 min (Table S3). In the most extreme case a
12
13 576 mantis held its pose for 6 h while sharing a cage with a predatory bird (Maldonado, 1970).
14
15 577 Deimatic behaviours were described as sustained and/or rhythmical (repeated) (*sensu* Blest,
16
17 578 1957*b*), around half the studies report on sustained behaviours, around 30% on rhythmical
18
19 579 and 15% on behaviours that have both sustained and rhythmical elements. We found no
20
21 580 reports describing movements that were performed only once and thus were neither sustained
22
23 581 nor rhythmical.
24
25
26
27
28
29
30

31 583 *(f) Stage of predation sequence in which deimatic behaviour is performed*

32
33 584 Although deimatic behaviours are thought to be performed during approach by a predator in
34
35 585 order for prey to be able to escape, only about 20% of studies reported deimatic behaviour
36
37 586 solely during the approach phase, while roughly half reported behaviours during subjugation,
38
39 587 and about 10% reported behaviours during both phases. These suggest that prior assumptions
40
41 588 about deimatic behaviours being deployed only during the approach phase may be
42
43 589 unfounded, and are consistent with our definition of deimatism as performed “during
44
45 590 approach or subjugation”. However, our ability to draw conclusions is limited because
46
47 591 around half of all studies (134/246, 54%) used humans as ‘predators’ to poke, drop or
48
49 592 otherwise disturb prey to evoke deimatic behaviour. Thus, it is possible that against natural
50
51 593 predators deimatic behaviour may be performed at an earlier stage. A key hypothesis to test is
52
53 594 that ‘defended’ species are more likely to display during subjugation whereas ‘undefended’
54
55
56
57
58
59
60

1
2
3 595 species display during approach. To understand the evolution of deimatic behaviour, it is
4
5 596 critical that an ecologically appropriate stimulus is used (see Section VIII.2).
6
7
8 597

9
10 598 **(3) Potential deimatic behaviours**

11
12 599 Confusion as to which behaviours are deimatic became obvious from our survey of the
13
14 600 literature. Common sources of ambiguity included defensive spray liquids, body inflation,
15
16 601 bioluminescent signals, alarm calls, vibrations, and electrical emissions. Given this
17
18 602 uncertainty, we briefly discuss these cases below and attempt to clarify the information
19
20 603 required to include or exclude them as deimatic, which will mostly depend on the receiver's
21
22 604 response.
23
24
25

26 605
27
28 606 *(a) Defensive sprays*

29
30 607 Edmunds (1974) described defensive sprays as retaliatory defences but the posturing before
31
32 608 the spray, such as that of a skunk, as deimatic. Skunks (Mephitidae) squirt strong-smelling
33
34 609 liquid at their attackers from glands (Medill, Renard & Larivière, 2011; Fisher &
35
36 610 Stankowich, 2018) and reflexive bleeders like horned lizards (*Phrynosoma* spp.) squirt blood
37
38 611 at their attackers (Sherbrooke *et al.*, 2001). More harmful sprays include the hot, caustic,
39
40 612 liquid sprays of bombardier beetles, stinging peppermint stick insect (*Megacrania batesii*)
41
42 613 sprays, and the entangling toxic 'glue' shot by termites (Eisner, 1970; Eisner & Adams, 1975;
43
44 614 Eisner, Yack & Aneshansley, 2001*b*; Eisner *et al.*, 2001*a*; Dossey, 2011). Interestingly,
45
46 615 bombardier beetles and skunks have warning colours as their primary defence, whereas
47
48 616 peppermint stick insects and horned lizards use crypsis. We hypothesise that posturing and/or
49
50 617 non-harmful sprays are deimatic in that they have an aversive effect when initially
51
52 618 encountered and then, on subsequent encounters, have an aposematic effect. The distinction
53
54 619 lies in whether the posturing before sprays are employed has a deimatic effect and whether
55
56
57
58
59
60

1
2
3 620 spraying the predator qualifies as retaliation (*sensu* Edmunds, 1974) rather than deimatism,
4
5 621 but no clear line has yet been drawn. Future work could focus on the effect of posturing and
6
7 622 the degree of physical harm done to the attacker during the spraying behaviour to disentangle
8
9 623 these defences.
10
11

12 624

14 625 *(b) Body inflation*

16 626 Body inflation, using gases or liquids, occurs in many species, including frogs in which it is
17
18 627 considered part of their deimatic behaviour (Martins, 1989). Body inflation is also used by
19
20 628 many reptiles and fish in which it has not been described as deimatic *per se*, but is considered
21
22 629 defensive (Badiane *et al.*, 2018). Pufferfish (Tetraodontidae) inflate their bodies with the
23
24 630 added effect of raising spines, which is assumed to make them more difficult to bite and/or
25
26 631 swallow, but the inflation also may elicit an aversive response qualifying this behaviour as
27
28 632 deimatic (Wainwright & Turingan, 1997). Similarly, during their deimatic behaviour
29
30 633 cephalopods use ‘sustained hyperinflation’; this may interfere with their circulation hinting at
31
32 634 a measurable cost to performing this behaviour (King & Adamo, 2006). It has been suggested
33
34 635 that their inflation in response to a perceived threat could have a deimatic effect, be an
35
36 636 aposematic signal, highlight weapons, and/or mechanically impede predation. Whether the
37
38 637 inflation process deters an attacker owing to induced fear of the inflated animal suddenly
39
40 638 looming, or whether the resulting large body size exceeds the gape limit of the attacker is
41
42 639 untested.
43
44

45 640

47 641 *(c) Electrical discharge*

49 642 Electrical signals are surprisingly ubiquitous in nature (England & Robert, 2021). The
50
51 643 electrical discharges generated by numbfishes (Narcinidae), electric rays (Torpedinidae), and
52
53 644 electric eels (*Electrophorus electricus*) could be deimatic behaviours. They are not typically
54
55
56
57
58
59
60

1
2
3 645 described as deimatic in the literature perhaps because it is mechanism focused (Sheridan,
4
5 646 1965; Mellinger *et al.*, 1978; Macesic & Kajiuura, 2009). Electrical signals are, however,
6
7 647 known to function in antipredator contexts in some species. Macesic & Kaijura (2009)
8
9 648 showed that the lesser electric ray (*Narcine brasiliensis*) generates electric organ discharges
10
11 649 against simulated predatory attacks. As there is still limited research into the use of electrical
12
13 650 discharges as a defence, it is currently unclear whether this should be considered retaliation to
14
15 651 make the prey less profitable, or whether it is a deimatic display. It may be speculated that
16
17 652 this could be context dependent, as the same charge could, for example, simply startle a
18
19 653 larger predator, whereas it could stun a smaller predator. The mechanism of defence could
20
21 654 therefore be related to both the type of predator and the type of prey (for example juvenile
22
23 655 lesser electric rays are capable of weaker discharges than adults), however further work is
24
25 656 needed to determine whether retaliation and deimatic behaviour can be separated in this
26
27 657 example. Behavioural studies on predator responses to electrical discharges are needed to
28
29 658 understand how they fit among antipredator defences especially in terms of retaliation and
30
31 659 aposematism.
32
33
34
35
36
37
38
39

40 661 (d) *Bioluminescence*

41
42 662 Bioluminescence, the chemical production of light by living organisms (Kahlke & Umbers,
43
44 663 2016), is used in anti-predatory contexts and can resemble deimatic behaviour (Stanger-Hall
45
46 664 & Oakley, 2019). Bioluminescence can be aposematic, as chemically defended adult and
47
48 665 larval fireflies elicit avoidance learning in anurans (De Cock & Matthysen, 2003), bats
49
50 666 (Leavell *et al.*, 2018), mice (Underwood, Tallamy & Pesek, 1997), and spiders (Long *et al.*,
51
52 667 2012), or it may 'frighten' potential predators (Lloyd, 1973). Esaias & Curl (1972)
53
54 668 hypothesised that dinoflagellate (*Gonyaulax* spp.) bioluminescent flashes function as a
55
56 669 protean display "*which startles or confuses the copepod*" (p. 901) suggesting both fleeing and
57
58
59
60

1
2
3 670 deimatism (Humphries & Driver, 1970; Edmunds, 1974; Driver & Humphries, 1989).
4
5 671 Similarly, lantern fish (Myctophidae) emit bioluminescent flashes in response to their
6
7 672 predators, southern elephant seals (*Mirounga leonina*), which result in longer prey capture
8
9 673 attempts (Goulet *et al.*, 2020). Where feasible, direct tests of predator responses could
10
11 674 identify examples of deimatism in bioluminescent systems.
12
13
14

15 675

16
17 676 *(e) Alarm calls and burglar alarms*

18
19 677 It is currently unclear whether ‘alarm calls’ (alerting conspecific receivers to a potential
20
21 678 danger), or ‘burglar alarms’ (attracting the attention of an enemy’s enemy) should be
22
23 679 considered as deimatic behaviour (Burkenroad, 1943; Haddock, Moline & Case, 2010;
24
25 680 Hanley & Widder, 2017). Vervet monkey (*Chlorocebus pygerythrus*) predator-specific alarm
26
27 681 calls signal the presence of a predator to conspecifics (Cheney & Seyfarth, 1981). However,
28
29 682 it could be speculated that the surprise (or ‘startle’) caused by an unexpected alarm call may
30
31 683 also directly deter predators if the prey’s call releases a threat-avoidance response. In
32
33 684 response to copepod (*Acartia tonsa*) attack some dinoflagellates (*Pyrodinium bahamense* and
34
35 685 *Lingulodinium polyedrum*) use bioluminescent flashes as ‘burglar alarms’ to draw in copepod
36
37 686 predators, but such flashes may also act to release a rapid threat response in the copepods
38
39 687 directly (Hanley & Widder, 2017).
40
41
42
43

44 688

45
46
47 689 *(f) Vibrations*

48
49 690 Substrate and airborne signals may constitute vibratory deimatism if they cause a threat-
50
51 691 avoidance response in an attacker. In many species disturbance-induced vibration increases
52
53 692 handling time and decreases predation risk (Bauer, 1976; Smith & Langley, 1978; Masters,
54
55 693 1979; Buchler, Wright & Brown, 1981; Lewis & Cane, 1990; Guedes *et al.*, 2012; Low,
56
57 694 2012), although some studies have found no evidence for protection against predation
58
59
60

1
2
3 695 (Gotch, 1997; Corey & Hebets, 2020). The studies that showed little protective value tested
4
5 696 vertebrate predators, which may not be the target receivers. For example, vibrations that can
6
7 697 successfully reduce parasitoid attacks (Low, 2012), and vibrations by spiders (Corey &
8
9 698 Hebets, 2020) could be deimatic to predatory piratid spiders but useless against birds or
10
11 699 predacious damselflies. However, further work is needed to determine definitively whether
12
13 700 these actions cause a threat-avoidance response in an attacker (and therefore are deimatic), or
14
15 701 whether the vibrations function to reduce attack by other mechanisms, such as making the
16
17 702 prey more challenging to handle.
18
19
20
21
22

703

704 (g) *Moth clicks*

25
26 705 Moth clicks, produced by tymbalation and stridulation (Corcoran & Hristov, 2014), have
27
28 706 been attributed many functions including startling predators and sonar jamming, and are
29
30 707 performed by both chemically defended and undefended species. Fullard & Fenton (1977)
31
32 708 suggested that while most sound-producing tiger moths in southern Ontario respond to
33
34 709 simulated bat echolocation calls with sound, others do not, and must be physically handled to
35
36 710 elicit defensive sound production. Playback experiments suggested that substrate-gleaning
37
38 711 bats are deterred by contact-elicited tiger moth clicks (Stoneman & Fenton, 1988; Bates &
39
40 712 Fenton, 1990). However, flight room interactions between wild bats and live tiger moths
41
42 713 suggest that while they click in response to being handled by a gleaning bat, in the wild
43
44 714 sound-producing tiger moths suffer similarly high mortality as silent species (Ratcliffe &
45
46 715 Fullard, 2005). Hristov & Conner (2005) showed that naïve big brown bats (*Eptesicus*
47
48 716 *fuscus*) are repelled by tiger moth clicks (four species of Arctiidae), but that they rapidly
49
50 717 learn to ignore the clicks unless the prey is also unpalatable. An intriguing, but untested,
51
52 718 possibility is that these sounds are more readily associated with chemical defence precisely
53
54 719 because they are deimatic, under the assumption that a negative signal can be more easily
55
56
57
58
59
60

1
2
3 720 associated with a negative consequence than can a neutral or positive acoustic signal
4
5 721 (Guilford & Dawkins, 1991; Ratcliffe & Fullard, 2005; Ter Hofstede & Ratcliffe, 2016).

6
7
8 722

9
10 723 *(h) Rattles*

11
12 724 The antipredator strategy of rattlesnakes, porcupines, and other animals that ‘rattle’ may
13
14 725 include deimatism (Edmunds, 1974). In rattlesnakes, the sound is produced by the impact of
15
16 726 keratin scales against each other (Gans & Maderson, 1973), while in porcupines the sound is
17
18 727 from knocking quills together and is made when a threat is perceived (Edmunds, 1974). Data
19
20 728 on how naïve and experienced predators respond to rattles are required to determine their
21
22 729 function. Presumably many predators can learn to associate the sound with a threat and thus
23
24 730 rattles likely have an aposematic function, while in naïve individuals the sound may have a
25
26 731 deimatic effect.

27
28
29
30
31 732

32
33 733 *(i) Facultative flatulence*

34
35 734 Herring (*Clupea harengus*) facultatively force air through the anus in an antipredator context
36
37 735 (Wahlberg & Westerberg, 2003). Air is apparently actively gulped at the water surface and
38
39 736 then later expelled from the herring’s anus when they are under duress. The resultant sounds
40
41 737 and bubbles may function as an acoustic and optic screen to confuse a pursuing predator
42
43 738 (Wahlberg & Westerberg, 2003)

44
45
46 739 The use of facultative flatulence in fish is still poorly understood, and it may be the
47
48 740 case that it is used more often in the context of inter-individual communication than defence
49
50 741 (Wilson, Batty & Dill, 2004). However, it may be speculated that rapid bursts of bubbles
51
52 742 could trigger reflexive responses in a predator, such as avoiding a crashing wave. Therefore,
53
54 743 facultative flatulence could have the potential to be a deimatic defence, but further work is
55
56 744 needed to determine definitively whether this is the case.

2
3 745
45 746 **IV. EVOLUTION OF DEIMATIC BEHAVIOUR**

7 747 Understanding the evolution of complex traits like deimatism is challenging, especially
8 748 because behaviours are difficult and costly to measure. Evolutionary models are required to
9
10 749 provide explicit hypotheses for experimental testing. Where data are available, comparative
11
12 750 approaches also provide important opportunities to generate and test hypotheses on the
13
14 751 evolution of deimatic behaviours. This can be done by establishing when and in what
15
16 752 lineages deimatism has evolved or been lost, and what ecological factors may be associated
17
18 753 with its evolution.
19
20
21
22
23

24 754

25
26 755 **(1) Evolutionary pathways to deimatism**

27
28 756 *Umbers et al.* (2017) formally proposed two potential pathways for the evolutionary
29
30 757 origins of deimatic behaviour; the ‘defence-first’ and ‘startle-first’ hypotheses. The defence-
31
32 758 first hypothesis suggests that the acquisition of some form of chemical defence or weapon
33
34 759 precedes the acquisition of a deimatic behaviour (itself also a defence). Under this
35
36 760 hypothesis, the acquired defence facilitates the evolution of, for example, a conspicuous
37
38 761 aposematic colour signal, the costs of which can be offset by concealment, revealing it only
39
40 762 when the prey perceives a threat. The defence-first hypothesis can also include revealing or
41
42 763 highlighting weapons, possibly from the ritualisation of counter-attack behaviour (Lieshout,
43
44 764 Elgar & Wilgenburg, 2005). For example, during their deimatic behaviour, many mantises
45
46 765 highlight their large raptorial forelimbs which are used in prey capture and retaliation
47
48 766 (*O’Hanlon et al.*, 2018; *Vidal-García et al.*, 2020). However, unless further defences are lost
49
50 767 upon the evolution of deimatic behaviour, the numerous examples of deimatism not
51
52 768 obviously associated with a chemical or weaponry defence require other evolutionary routes.
53
54
55
56
57
58
59
60

1
2
3 769 The startle-first hypothesis suggests that the act of performing the behaviour itself has
4
5 770 protective value and can allow the evolution of further defences. Given our objections above
6
7
8 771 concerning the use of the word ‘startle’, perhaps ‘behaviour-first hypothesis’ is a better name.
9
10 772 Vidal-García *et al.* (2020) found indirect evidence to support this behaviour-first hypothesis,
11
12 773 as they reported that wings were used by 29 of 31 displaying mantis species including 11
13
14 774 species in relatively basal phylogenetic positions that lacked hidden colours. In a behavioural
15
16
17 775 study, Holmes *et al.* (2018) showed that movement alone can be protective but that a
18
19 776 combination of colour and movement increased survival. Similarly, using a robotic moth and
20
21 777 wild black-capped chickadees (*Poecile atricapillus*), Kang, Zahiri & Sherratt (2017) showed
22
23 778 that prey movement alone, without other defensive components like colours, can elicit
24
25
26 779 responses consistent with responses to deimatic behaviour in birds.

27
28 780 Flash behaviour – repeated signalling while fleeing that inhibits predator pursuit –
29
30 781 could represent an intermediate step in either the startle-first or defence-first trajectories; after
31
32
33 782 signals are obtained but before they are used in deimatic behaviour (Umbers *et al.*, 2017)
34
35 783 (Table S2). In their study of the *Pleurodema* frogs, Faivovich *et al.* (2012) mapped flash
36
37 784 behaviour and deimatic behaviour on a phylogeny and suggested that deimatic behaviour
38
39 785 occurs in more derived species and flash behaviour in more basal species. However, it is
40
41
42 786 unclear how flash behaviour and deimatic behaviour were defined and quantified (Faivovich
43
44 787 *et al.*, 2012). Further comparative analyses that map the evolution of flash behaviour and
45
46 788 deimatic behaviour are needed to test this hypothesis.

47
48
49 789

50 51 790 **(2) Modelling the evolution of deimatic behaviour**

52
53 791 Theoretical models of deimatic behaviour have so far been mostly descriptive, qualitative
54
55 792 arguments, although mathematical models of related phenomena have been developed.

56
57
58 793 Theory in this area is necessary to formalise arguments and make testable predictions. Below
59
60

1
2
3 794 we highlight key considerations when developing mathematical models of deimatic
4
5 795 behaviour.

6
7
8 796 The evolution of antipredator defences is best considered as a co-evolutionary
9
10 797 process, in which any adaptation in prey that reduces their vulnerability to predation also
11
12 798 affects the nature of selection on predators and *vice versa* (Dawkins & Krebs, 1979; Abrams,
13
14 799 2000). A self-consistent co-evolutionary model (Houston & McNamara, 2006) of the
15
16 800 evolution of deimatic behaviour therefore requires an understanding of the nature of selection
17
18 801 on *both* predators and prey, with the aim of characterising their plausible co-evolutionary
19
20 802 states (such as a mutual equilibrium and/or stable limit cycle; Otto & Day, 2011).
21
22 803 Importantly, deimatism may not necessarily involve co-evolution. It might simply be a result
23
24 804 of the ‘wiring’ of the attacker’s brain and cognitive processes that developed in other
25
26 805 contexts, thereby requiring no co-evolution and no learning. However, the fitness
27
28 806 consequences of these processes should be considered for both the attacker and the displaying
29
30 807 individual. Several co-evolutionary models of predator–prey interactions have been
31
32 808 developed (Abrams, 2000; Mougi & Iwasa, 2010; Tien & Ellner, 2012; Bateman, Vos &
33
34 809 Anholt, 2014), but we are not aware of any developed specifically for understanding the
35
36 810 evolution of deimatic behaviour.

37
38
39
40
41
42 811 Deimatic behaviours are typically not primary defences but rather back-up defences
43
44 812 deployed at the prey’s discretion (Umbers, Lehtonen & Mappes, 2015). This can be
45
46 813 formalised in modelling terms by viewing deimatic behaviours as one defence in a sequence
47
48 814 of antipredator defences (Fig. 2). If the primary defensive strategy is highly effective in
49
50 815 preventing predation, this may impede selection on further defences that are invoked only
51
52 816 when the primary defence fails (Britton, Planqué & Franks, 2007; Wang *et al.*, 2019). Such
53
54 817 ‘strategy blocking’ may lead to cross-species associations between primary and subsequent
55
56 818 defences (such as deimatism) mediated by factors that affect the upper limit on the primary
57
58
59
60

1
2
3 819 defence, such as body size (Kang *et al.*, 2017) (for further discussion of body size, see
4
5 820 Section IV.4a). From an evolutionary perspective, perhaps the most fundamental question is:
6
7 821 *what is the selective advantage for a predator responding to deimatic behaviour?* It is a
8
9 822 behavioural response that comes at the cost of energy expenditure and opportunities missed,
10
11 823 so what are its benefits? If it is a rapid response to a potential threat (Simons, 1996), it may
12
13 824 save the life of the receiver, or prevent injury. Signal detection theory quantifies the optimal
14
15 825 trade-off between type I error (such as twigs treated as snakes, ‘false alarms’) and type II
16
17 826 errors (snakes treated as twigs, ‘misses’) (Leavell & Bernal, 2019). If the costs of mistaking a
18
19 827 snake for a twig far outweigh the costs of mistaking a twig for a snake, then a conservative
20
21 828 threshold with a high false alarm rate would be optimal, even when the likelihood of the
22
23 829 stimulus coming from a true threat is small (Castellano & Cermelli, 2015). While signal
24
25 830 detection models identify the optimal response under uncertainty, speed–accuracy trade-offs
26
27 831 need to be included (Chittka, Skorupski & Raine, 2009). If the stimulus is sudden, such as
28
29 832 that caused by dangerous events like the rush of a potential predator or a tree falling, then
30
31 833 quick action will be favoured over careful deliberation. As Janzen *et al.* (2010, p. 11659),
32
33 834 puts it “*pause a millisecond to ask whether that eye belongs to acceptable prey or to a*
34
35 835 *predator, you are likely to be—and it takes only once—someone’s breakfast*”.

36
37
38
39
40
41
42 836 Models that combine signal detection and speed–accuracy trade-offs have been
43
44 837 developed and take the form of sequential sampling models in which additional inspections to
45
46 838 gain more information come at a cost (e.g. Getty, 1996; Abbott & Sherratt, 2011).
47
48 839 Complementary models have separated the two processes almost entirely. For example,
49
50 840 motivated by empirical evidence, Trimmer *et al.* (2008) represented mammalian brains as
51
52 841 having two decision-making systems, both Bayesian in nature but acting at different speeds.
53
54 842 The first quick-but-inaccurate thalamic decision is assumed to be based on a one-off
55
56 843 application of signal-detection theory involving a simple (and conservative) threshold for
57
58
59
60

1
2
3 844 treating stimuli as threats, whereas the slow-but-accurate cortical decision is based on the
4
5 845 sequential probability ratio test (SPRT) as more evidence governing how to act is gathered
6
7 846 over time (Wald, 1945; Castellano, 2015). Natural selection appears to have favoured an ‘act
8
9 847 now, think later’ response to certain stimuli because only quick action can save the observer’s
10
11 848 life and, like many behaviours, this response can be exploited by potential prey. Modelling
12
13 849 can help clarify why the responses are rapid, and how they continue to be maintained despite
14
15 850 a high propensity for false alarms.

16
17
18
19 851 Finally, there are other features of the response to deimatic behaviour that can be
20
21 852 understood using mathematical models. For example, the prior presentation of a stimulus
22
23 853 associated with an undesirable event tends to generate a more vigorous response to an
24
25 854 unrelated stimulus (Brown, Kalish & Farber, 1951); a result readily understood through
26
27 855 Bayesian conditioning models (Bach, 2015). Likewise, habituation to a stimulus can be
28
29 856 modelled through Bayesian learning in which the conditional probability of the signaller
30
31 857 being a threat is updated over time as more information is gained. A related set of questions
32
33 858 revolve around why some species’ deimatic behaviours inhibit would-be predators long after
34
35 859 the initial reflex-like response. Of course, even if rapid habituation occurs under experimental
36
37 860 conditions, then it may not be realised under more natural conditions. In particular, it is
38
39 861 possible that some observers and/or signallers would flee following a deimatic display if it
40
41 862 they were able to do so. Even if only a small proportion of attackers or signallers respond in
42
43 863 this way, it can still be selected for as a last-resort defence even if there is no long-lasting
44
45 864 inhibitory effect from the display.

46
47
48
49
50
51 865

52 53 866 **(3) Comparative analyses and the evolution of deimatic behaviour**

54
55 867 Crane (1952), Edmunds (1972, 1976), Blest (1957*b*), and Brodie (1983) on mantises, moths
56
57 868 and salamanders were the first to compare the diversity and systematic patterns of deimatic
58
59
60

1
2
3 869 behaviour among species. The detailed descriptions and observations of deimatic behaviour
4
5 870 now available allow phylogenetic analyses (Vidal-García *et al.*, 2020) to investigate when
6
7 871 and why deimatism evolves and is lost. Kang *et al.* (2017) assessed the evolution of hidden
8
9 872 hindwing colours in erebid moths (Noctuoidea: Lepidoptera) assuming that their hidden
10
11 873 colours are used in deimatic behaviour. Their results suggested that basal erebid moths lack
12
13 874 hidden colours, that hidden colours are a derived trait, and that it has evolved multiple times
14
15 875 across the family. In phylogenetically controlled analysis of hidden colours in a further five
16
17 876 insect taxa, Orthoptera, Mantodea, Phasmatodea, Saturniidae and Sphingidae, Loeffler-
18
19 877 Henry, Kang & Sherratt (2019) found evidence for the repeated evolution of hidden
20
21 878 contrasting colours dozens of times among these five groups. A comparative analysis by
22
23 879 Bura, Kawahara & Yack (2016) found that what they termed acoustic startle defences
24
25 880 (Dookie *et al.*, 2017) have evolved multiple times in caterpillars from multiple lepidopteran
26
27 881 subfamilies in Sphingidae and Saturniidae. They found that short clicking sounds were
28
29 882 typically followed by regurgitation while longer, louder sounds were not and thus the short
30
31 883 clicking sound form seems to be associated with the expulsion of chemical defence. The
32
33 884 ancestral state reconstruction of deimatic displays in 58 mantis genera by Vidal-García *et al.*
34
35 885 (2020) included behavioural data as well as descriptions of colour patterns and body size on
36
37 886 the presence and absence of deimatic behaviour. Their findings suggest that some form of
38
39 887 camouflage without deimatic behaviour is the ancestral state in mantises, and that it has
40
41 888 evolved at least four times across the Mantodea (Vidal-García *et al.*, 2020). They also show
42
43 889 that deimatic behaviour has evolved in species without any associated colour patterns and
44
45 890 that inclusion of behavioural data is important. By contrast, placing data from 25 of Brodie's
46
47 891 salamander descriptions into a phylogenetic context shows gains, losses, and variability of
48
49 892 deimatic behaviour, but deimatic behaviour is found in the most basal lineages included in
50
51
52
53
54
55
56
57
58
59
60

1
2
3 893 the tree (Fig. 4). These studies all confirm the conclusions of the earlier comparative studies,
4
5 894 that deimatic behaviours are frequently gained and lost as a lineage diversifies.
6

7
8 895 The processes driving gains and losses of deimatic behaviour are unclear. In praying
9
10 896 mantises there is a hint that deimatic behaviour evolved in response to the evolution of birds,
11
12 897 appearing roughly 60 million years ago (Vidal-García *et al.*, 2020). So far, no phylogenetic
13
14 898 comparative studies have included the required data to test hypotheses on ecological drivers
15
16 899 such as predator diversity, population density, habitat type and activity time, but such
17
18 900 analyses would make a valuable contribution to elucidating the evolutionary timing and
19
20 901 ecological correlates of deimatic behaviour.
21
22
23

24 902

25 26 903 **(4) Traits associated with the evolution of deimatic behaviour**

27
28 904 Several hypotheses have been proposed suggesting that the evolution of deimatic behaviour
29
30 905 is related to body size, degree of unprofitability, and phenology.
31
32

33 906

34 35 907 *(a) Deimatic behaviour and body size*

36
37 908 The literature provides mixed support for the hypothesis that larger species are more likely to
38
39 909 perform deimatic behaviours. Kang *et al.* (2017) suggested that hidden colours are more
40
41 910 common in large species than in small species of Erebiidae moths. In a taxonomically broader
42
43 911 study, Loeffler-Henry *et al.* (2019) also found evidence of a positive correlation between
44
45 912 body size and hidden colouration for four insect taxa (Orthoptera, Phasmatidae, Mantidae,
46
47 913 Saturniidae) but not for Sphingidae. More nuanced still, particular colours may be correlated
48
49 914 with body size. Emberts *et al.* (2020) studied 26 species of leaf-footed bugs (Coriidae) and
50
51 915 found an association between large size and deimatic behaviour only in species with white
52
53 916 hidden patches, but not in those with red/orange patches. These studies suggest that certain
54
55 917 colours of signals revealed by deimatic behaviour are more common in larger species but do
56
57
58
59
60

1
2
3 918 not address whether deimatic behaviour itself is more common in larger species. However, a
4
5 919 phylogenetically controlled analysis on 58 praying mantis species that included behaviour,
6
7 920 sound production, and hidden colours found no support for the hypothesis that larger species
8
9 921 were more likely to exhibit deimatic behaviour (Vidal-García *et al.*, 2020). Discrepancies
10
11 922 between this study and that of Loeffler-Henry *et al.* (2019) are likely due to differences in the
12
13 923 sizes of species sampled. Some deimatic species lacked hidden colouration suggesting that a
14
15 924 relationship between the presence of hidden colours and size does not extend to deimatic
16
17 925 behaviour *per se*.

18
19 926 If larger prey have deimatic behaviour because they are more likely to be attacked due
20
21 927 to their profitability as a larger meal, then why do so many deimatic behaviours include an
22
23 928 apparent body size increase? One hypothesis is that it is not their profitability, but their
24
25 929 conspicuousness that puts larger species under greater predation pressure (Pembury Smith &
26
27 930 Ruxton, 2021). If this is true, then appearing to become larger only when performing a
28
29 931 deimatic behaviour would lower predation risk only if the behaviour was performed once the
30
31 932 prey had already been detected. One species which may be using this defence is the European
32
33 933 cuttlefish. Underwater trials with young laboratory-reared cuttlefish released into natural
34
35 934 habitats demonstrated that predatory groupers (*Serranus cabrilla*) ceased their attack
36
37 935 sequence when the cuttlefish rapidly deployed their deimatic body pattern (Fig. 11) while
38
39 936 flattening their body to create the illusion of a larger body size. When this deimatic behaviour
40
41 937 was not deployed, attacks continued and some cuttlefish were eaten (Hanlon & Messenger,
42
43 938 1988).

44
45 939 Additionally, larger prey may be more effective at confusing predators or eliciting the
46
47 940 looming reflex in receivers during deimatic behaviour (see Section II.7b). Alternatively, an
48
49 941 increase in size could be related to making the prey more challenging to consume,
50
51 942 particularly if the increased size exceeds the maximum gape size of the predator. New theory
52
53
54
55
56
57
58
59
60

1
2
3 943 and further research are needed to determine how body size and deimatic behaviour interact
4
5 944 considering trophic level, predator diversity, and other ecological factors.
6
7
8 945

9
10 946 *(b) Deimatic behaviour and prey profitability*

11
12 947 Many textbooks suggest that deimatic behaviour is performed by ‘undefended’ species and is
13
14 948 therefore a ‘bluff’. We disagree with this description for two reasons. One, we argue that
15
16 949 deimatic behaviour itself has protective value and therefore cannot be a bluff, and two this
17
18 950 stands regardless of the presence of any further defences such as repellent tastes (Rowland,
19
20 951 Ruxton & Skelhorn, 2013), toxins (Barnett *et al.*, 2012), weapons (Speed & Ruxton, 2005),
21
22 952 protean escape (Edmunds 1974), and impenetrable armour (Wang *et al.*, 2018). In the
23
24 953 venomous cottonmouth snake (*Agkistrodon piscivorus*) the use of deimatic behaviour has
25
26 954 been found to be a reliable indicator of an individual’s willingness to strike (Glaudas &
27
28 955 Whine, 2007). Beyond this we are not aware of any formal studies testing what drives or
29
30 956 correlates with deimatic behaviours and the presence of further defences. The main challenge
31
32 957 is defining ecologically relevant unprofitability and a model taxon.
33
34
35
36
37
38
39

40 959 *(c) Deimatic behaviour and phenology*

41
42 960 Kim *et al.* (2020) compiled data on colour, phenology, and abundance for 1,568 macro-
43
44 961 lepidopteran species on three continents (Asia, Europe, and North America) and found that
45
46 962 species with hidden contrasting colours that are putatively used in deimatic behaviour appear
47
48 963 later in the season than the species with other colour defences. This finding is interesting as it
49
50 964 may be expected that deimatic behaviour would be most effective against naïve predators,
51
52 965 and therefore would be most protective earlier in the season. However, it could be that a
53
54 966 protective effect against naïve predators may be quickly diluted by predator learning. Thus,
55
56 967 the fitness benefit of appearing early in the season may not be significant because this
57
58
59
60

1
2
3 968 protective effect does not contribute significantly to the survival of adult insects (until they
4
5 969 reproduce). On the other hand, a protective effect through mimicry may remain stable
6
7
8 970 because predators' avoidance learning remains for longer and more consistently (and perhaps
9
10 971 reinforced continuously through their experience with various aposematic prey).

11
12 972 Some species with deimatic behaviours may gain protection because they reveal a
13
14 973 signal that is a Batesian mimic of defended species. This could be an effective defence if
15
16 974 predators generalise signals or if those signals are highly effective against naïve predators. If
17
18
19 975 species with deimatic behaviours derive a selective advantage by delaying their activities
20
21 976 until local predators have learned to avoid aposematic signals, it would be interesting to test
22
23 977 how this fits into mimic–model systems in Batesian mimicry theory (Waldbauer, Sternburg &
24
25 978 Maier, 1977).

26
27
28 979

30 980 **V. ONTOGENY OF DEIMATIC BEHAVIOUR**

31
32
33 981 Juveniles and adults differ in important ecological and morphological ways and thus may
34
35 982 employ different defences. However, ontogenic changes in the presence and absence of
36
37 983 deimatic behaviour, and more subtle differences in their performance during development,
38
39 984 are only known for multiple life stages in a few species (Table S4).

40
41
42 985 In animals that undergo 'complete' metamorphosis, the differences between juveniles
43
44 986 and adults may require different defensive strategies due to differences in mobility, habitat,
45
46 987 and diet. Holometabolous insects provide many examples of deimatic behaviour at only one
47
48
49 988 life stage, and we found no descriptions of deimatism for both larval and adult life stages
50
51 989 (Table S4). Lepidopteran larvae (caterpillars) provide excellent examples of deimatic
52
53 990 behaviour as juveniles but the presence of deimatic behaviours in their adult forms is often
54
55 991 unknown. However, in peacock butterflies the reverse is true: adults use deimatic behaviour,
56
57
58 992 whereas we found no evidence of deimatic behaviour in their caterpillars. Ambystomid
59
60

1
2
3 993 salamanders also undergo a dramatic metamorphosis, only after which do they exhibit
4
5 994 deimatic behaviour. In Anderson's crocodile newt (*Echinotriton andersoni*), aquatic larvae
6
7
8 995 do not posture, but just one day after they reabsorb their gills terrestrial juveniles can perform
9
10 996 an extreme version of the deimatic behaviours seen in mature adults, in which they can bring
11
12 997 their ribs forward at an angle of 90° to their spine to pierce the skin (Brodie, Nussbaum &
13
14 998 Digiovanni, 1984). The posturing behaviour could be deimatic, with the protrusion of ribs
15
16
17 999 perhaps preparation for retaliation, or a deterrent by exceeding a predator's gape. Such
18
19 1000 differences between adult and juvenile defences may reflect adaptations to their different
20
21 1001 aquatic and terrestrial habitats.

22
23
24 1002 For animals that undergo relatively gradual changes in morphology over their life
25
26 1003 stages, data on changes in deimatic behaviour with ontogeny were available for some
27
28 1004 mantises, orthopterans, and squid (Table S4). The double eye-spot mantis (*Stagmatoptera*
29
30 1005 *biocellata*) uses crypsis as its sole method of predator defence in the first and second instar,
31
32
33 1006 whereas intermediate instars (3–7) use both crypsis and deimatic behaviours, and adults
34
35 1007 primarily use deimatic behaviours (Balderrama & Maldonado, 1973). The authors suggested
36
37 1008 that relying on deimatic displays may be too risky when individuals are small and relatively
38
39 1009 easy prey, and that their stick-like morphology may allow camouflage. Adults with their
40
41 1010 more prominent head may prevent them from mimicking sticks as effectively, reducing their
42
43 1011 camouflage and increasing pressure for the evolution of deimatism as a secondary defence. In
44
45 1012 the mantis *Angela guianensis*, adults use deimatic wing displays, while juveniles rely on
46
47 1013 running and dropping. In the Texas unicorn mantis (*Phyllovates chlorophaea*) and Peruvian
48
49 1014 shield mantis (*Choeradodis rhombicollis*) juveniles also run and drop in defence. The
50
51 1015 deimatic behaviour of adult *P. chlorophaea*, on the other hand, reveals yellow and black
52
53 1016 bands on their dorsal abdomen, while that of adult *C. rhombicollis* includes rearing up and
54
55 1017 posturing towards the attacker. Juveniles also rely on fleeing in several orthopterans. In the
56
57
58
59
60

1
2
3 1018 katydid *Scorpiorinus fragilis* (Pseudophyllinae), nymphs rely on escape while adults reveal
4
5 1019 their yellow dorsal abdomen in response to touch by lifting their wings which produces a
6
7 1020 stridulatory sound (Robinson, 1969). Adults of the stick insect, *Metriotes diocles* raise their
8
9 1021 wings in a deimatic display while nymphs tend to drop and use thanatosis to avoid
10
11 1022 consumption (Robinson, 1969). Differences during ontogeny have also been reported in the
12
13 1023 defensive behaviour of two species of squid, Atlantic brief squid (*Lolliguncula brevis*) and
14
15 1024 longfin inshore squid (*Doryteuthis pealeii*) (York & Bartol, 2016). Paralarvae (hatchlings) of
16
17 1025 *D. pealeii* were more likely to use transparency in response to predators whereas juveniles
18
19 1026 and adults of *L. brevis* were more likely to perform deimatic behaviours. It is possible that
20
21 1027 relying on crypsis alone for adults is too costly or risky, or that deimatic behaviour in
22
23 1028 juveniles is less effective, or perhaps both. By contrast, juvenile cottonmouth snakes
24
25 1029 (*Agkistrodon piscivorus*) are more likely than adults to use deimatic behaviour (Glaudias,
26
27 1030 Winne & Fedewa, 2006). A possible explanation is that adult cottonmouths may face a
28
29 1031 sufficiently low predation risk that the energetic costs of deimatic behaviour are not justified.
30
31 1032 Together, these findings suggest a species-specific use of deimatic displays at different life
32
33 1033 stages.

34
35
36
37
38
39
40 1034 Changes in deimatic behaviour across development can be more subtle than simple
41
42 1035 presence or absence. For example, in European cuttlefish, hatchlings, juveniles and adults use
43
44 1036 different body patterns and postures as deimatic displays (Hanlon & Messenger, 1988).
45
46 1037 Similar examples of subtle changes in deimatic behaviour during development have been
47
48 1038 observed in the mountain katydid (*Acripeza reticulata*). Subadults have orange and black
49
50 1039 intersegmental abdominal membranes which are visible when they move (Table S4). Adults,
51
52 1040 by contrast, have large mottled brown wings which completely hide their red, blue, and black
53
54 1041 striped abdominal surface. Umbers & Mappes (2015) found that when performing deimatic
55
56 1042 behaviour, subadult mountain katydids held their position for longer than adults, perhaps
57
58
59
60

1
2
3 1043 because they lack the tough wings of adults. Lacking tough wings may mean juveniles rely
4
5 1044 more on their deimatic behaviour and the aposematic signal it reveals which could select for
6
7 1045 longer display times (Baker, 2019). Because subadults lack wings and therefore cannot fly,
8
9 1046 their extended display may compensate for their reduced opportunity to escape. By contrast,
10
11 1047 the Western Australian katydid (*Mygalopsis marki*) develops auditory deimatic behaviour
12
13 1048 very early in life. Both adults and nymphs stridulate, producing a sound within their head
14
15 1049 capsule, and this behaviour is maintained throughout ontogeny despite major morphological
16
17 1050 changes (Bailey & Sandow, 1983), however nymphs are more likely to attempt to escape
18
19 1051 during the early stages of the predation sequence and stridulate when caught, whereas adults
20
21 1052 posture while stridulating when faced with a predator. This example may suggest that the
22
23 1053 constraints on deimatic behaviours involving visual signals and auditory signals may vary,
24
25 1054 and may arise at different stages across ontogeny.

26
27
28
29
30
31 1055 The level of cognition involved in prey display performances is mostly undocumented
32
33 1056 but there is some evidence that individuals improve their displays as they develop.
34
35 1057 Sunbitterns (*Eurypyga helias*) are large birds that reveal eyespots on their wings when
36
37 1058 threatened. Thomas & Strahl (1990) described young sunbitterns practicing their wing
38
39 1059 displays from seven days old and performing full wing displays from 12 days old until they
40
41 1060 left the nest two to three weeks later. They observed nestlings displaying to falling leaves and
42
43 1061 butterflies, perhaps mistakenly or instinctively. These results may suggest that the risk of
44
45 1062 drawing attention to themselves on the nest before they can fly is outweighed by the benefit
46
47 1063 of mastering the behaviour before fledging, a hypothesis for future testing.

48
49
50
51 1064 Taken together, the available evidence seems to support the view that deimatic
52
53 1065 behaviours are more likely to be found in adult animals, but whether this is a research bias or
54
55 1066 is biologically important is unclear. Body size could be a factor driving the presence and
56
57
58
59
60

1
2
3 1067 absence of displays at different life stages (see Section IV.4a), but this and alternative
4
5 1068 explanations such as differing niches or activity levels remain to be tested.
6
7
8 1069

10 1070 **VI. CAUSATION OF DEIMATIC BEHAVIOUR**

11
12 1071 Tinbergen (1963) described causation as the physiology of behaviour, encompassing both the
13
14 1072 underlying molecular, physiological and cognitive processes, now more commonly called
15
16 1073 mechanisms. We summarise what is known about triggers that release deimatic behaviour,
17
18 1074 and special mechanisms by which the behaviours are performed. Predator cognition and
19
20 1075 behaviour drive the evolution of deimatic behaviour and we discuss the putative
21
22 1076 psychological mechanisms involved (Fawcett, Marshall & Higginson, 2015).
23
24
25

26 1077 27 28 1078 **(1) Releasers of deimatic behaviour**

29
30 1079 Deimatic behaviours may be released by being touched, hearing a sound, detecting a smell, or
31
32 1080 seeing a visual signal (Table S3). Experimental evidence from studies using ecologically
33
34 1081 relevant predators is rare, with most data coming from experiments where predation is
35
36 1082 simulated by humans. Triggers in some sensory modes may be more likely to release
37
38 1083 deimatic behaviour than others, more likely to release different components of deimatic
39
40 1084 behaviour, and/or release different levels of intensity. In some katydids and mantises most
41
42 1085 individuals perform their deimatic behaviour in response to tactile rather than visual stimuli,
43
44 1086 and more invasive stimuli evoke more intense displays (Umbers & Mappes, 2015; O'Hanlon
45
46 1087 *et al.*, 2018). Maldonado (1970) experimentally investigated the effects of visual and tactile
47
48 1088 triggers on mantises. When visual cues were obliterated by covering the eyes, tactile cues still
49
50 1089 released the full display, however, a visual releaser resulted in a longer display. More work
51
52 1090 needs to be done to determine which cues, signals, and their components are most effective in
53
54 1091 releasing deimatic behaviour. Mechanistic and sensory constraints, including noise, probably
55
56
57
58
59
60

1
2
3 1092 determine the type of stimuli prey respond to and the fitness consequences of their responses
4
5 1093 (Cooper & Blumstein, 2015).
6
7
8 1094

9
10 1095 **(2) Mechanisms of components of deimatic behaviour**
11

12 1096 Deimatic behaviour can target any sensory mode although most work has focused on visual
13
14 1097 components. We assume many of the physiological and psychological mechanisms
15
16 1098 associated with deimatic behaviour have not evolved *de novo*, but were co-opted from other
17
18 1099 functions. For example, the muscles used in butterfly flight are presumably the same as those
19
20 1100 used to move their wings during deimatic behaviour. We note that well-understood pathways
21
22 1101 present opportunities to measure costs and their evolutionary history.
23
24
25

26 1102
27
28 1103 *(a) Visual components: colour, movement, and size*
29

30 1104 Many deimatic behaviours reveal colour patterns hidden under wings, legs, fins, bellies,
31
32 1105 inside mouths, and/or on flaps of neck skin. To date there is no evidence that colours
33
34 1106 associated with deimatic behaviour are produced *via* mechanisms different from those used in
35
36 1107 other signals, although some observations suggest that hiding colour patches could reduce
37
38 1108 maintenance costs. For example, in mountain katydids that have one tegmen missing,
39
40 1109 abdominal colours are bleached where they are exposed but retained where they are covered
41
42 1110 (K.D.L. Umbers, personal observation).
43
44
45

46 1111 Most insect deimatic behaviour includes the movement of legs and/or wings. The
47
48 1112 mechanisms of movement involved in deimatic behaviour have been directly manipulated in
49
50 1113 the nervous system of praying mantises. Maldonado (1970) determined that the components
51
52 1114 of deimatic behaviour performed varied depending on which nerves were severed. A cut
53
54 1115 between the suboesophageal and prothoracic ganglia resulted in only the head and mouth
55
56
57
58
59
60

1
2
3 1116 responding to visual stimuli, and the rest of the body required tactile stimulation to respond
4
5 1117 (Maldonado, 1970).

7 1118 The 'unken reflex', named after the fire-bellied toads 'Feuerunke' (Löhner, 1919), is a
9
10 1119 proximate cause of deimatic behaviour but little is known about its mechanistic
11
12 1120 underpinnings. Typically only applied to amphibians, it manifests as a rigid arching or lifting
13
14 1121 of the body, legs, and/or tail in which ventral surfaces become visible and sometimes body
15
16 1122 parts are 'hypnotically' swayed (Brodie, 1977). For example, Colombian four-eyed frogs
17
18 1123 (*Pleurodema brachyops*) lift their hind quarters to reveal eyespots and colour patches, and
19
20 1124 highlight poison glands (Martins, 1989). In some salamanders, deimatic behaviour includes
21
22 1125 their ribs penetrating the skin in special areas of the integument with poison glands. Whether
23
24 1126 this is caused by the same process as the posturing is unclear (Brodie, 1977, 1983; Nowak &
25
26 1127 Brodie, 1978).

28
29
30 1128 Few morphological structures seem to have evolved for use in deimatic behaviour. A
31
32 1129 promising candidate, however, is 'hooding' in snakes (Table S3). During hooding, cobras
33
34 1130 (*Naja* spp.) use eight muscles and putatively novel nervous rewiring to elevate and protract
35
36 1131 the ribs, while flattening and expanding the neck (Young & Kardong, 2010; Jara &
37
38 1132 Pincheira-Donoso, 2015). Other specialised structures may exist and future work beyond
39
40 1133 traditional model systems will probably highlight other traits.

41
42
43 1134 Cephalopods provide a clear exception to movement of large body parts in deimatic
44
45 1135 behaviour, with their colour patterns displayed and changed by chromatophores (Langridge,
46
47 1136 2009). Chromatophore colour change is controlled by the dispersal and concentration of
48
49 1137 pigments *via* intracellular innervated radial muscles (Messenger, 2001; Hanlon & Messenger,
50
51 1138 2018). The most well-studied cephalopod deimatic behaviour is that of the European
52
53 1139 cuttlefish, which produce dark rings around the eyes and dark eyespots on the dorsum
54
55 1140 (Holmes, 1940; Langridge, Broom & Osorio, 2007) (Fig. 1I). Their deimatic pattern is
56
57
58
59
60

1
2
3 1141 complex, comprising six signalling elements that can be expressed in different combinations:
4
5 1142 (1) flattened body posture; (2) paling of the skin; (3) paired mantle spots that look like eyes;
6
7 1143 (4) a dark fin line; (5) a dark eye ring; and (6) a dilated pupil. They can also produce
8
9
10 1144 directional displays presenting deimatic patterning only towards the predator and cryptic
11
12 1145 patterning away from the predator (Langridge, 2006), indicating that their neural mechanisms
13
14 1146 allow targeted responses.

15
16
17 1147 Movements included in deimatic behaviour are not restricted simply to the performer
18
19 1148 changing state from resting to displaying, they may continue throughout the performance as
20
21 1149 re-orienting or rhythmical repetition. For example, during deimatic behaviour mountain
22
23 1150 katydids reorient their distasteful brightly coloured abdomen towards their attacker (Umbers
24
25 1151 & Mappes, 2015; Umbers *et al.*, 2019). The peacock butterfly's rhythmic deimatic behaviour
26
27 1152 involves their wings being opened and closed in succession at a constant rate (Blest, 1957*b*).
28
29 1153 The devil's flower mantis (*Indolomantis diabolica*) moves its outstretched forelimbs back
30
31 1154 and forth in a pendulum-like fashion. Many salamanders sway or undulate their tails
32
33 1155 'hypnotically' throughout their display. The efficacy of displays with and without repeated
34
35 1156 movement has not been compared but in many cases rhythmical movements are associated
36
37 1157 with sound production which adds further complexity (Blest, 1957*b*; Vallin *et al.*, 2005)
38
39 1158 (Table S3). Rhythmic signals may be much more effective in stimulating the receiver than
40
41 1159 sustained displays if they avoid sensory adaptation in the predator. Signalling at random time
42
43 1160 intervals may be more effective still if doing so eliminates synchronous sensory adaptation.
44
45
46
47
48

49 1161

50
51 1162 *(b) Acoustic components: sounds and vibration*

52
53 1163 Sounds (i.e. air and water-borne vibrations) and vibrations (i.e. solid-borne vibrations) are
54
55 1164 widely used in defence across several taxa (Low, Naranjo & Yack, 2021). We discussed
56
57 1165 vibrations in the context of deimatic behaviour in Section III.3*f*, and alarm calls in Section
58
59
60

1
2
3 1166 III.3e. Here we focus on sounds produced during an encounter with a predator which have
4
5 1167 been proposed to function in aposematism, jamming echolocation calls, and as deimatic
6
7
8 1168 behaviour (see Low *et al.*, 2021). Continuous sound production is presumably too costly in
9
10 1169 terms of conspicuousness or energy (Low *et al.*, 2021). One notable exception occurs in
11
12 1170 cicadas which as a group produce incessant mate-attraction calls *via* tymbalation [the flexing
13
14 1171 of corrugated regions of exoskeleton (tymbals)] that may have a dual function in
15
16 1172 aposematism (Simmons, Wever & Pylka, 1971). Cicadas can drive bird predators out of
17
18 1173 forests both due to the dangerously loud and painful sound, and its disruption to their
19
20 1174 communication (Simmons *et al.*, 1971). Their sound can certainly drive human visitors away
21
22
23 1175 (K.D.L. Umbers & J.A. Endler, personal observations).

24
25
26 1176 Sounds used in defence are produced by a huge diversity of body parts or specialised
27
28 1177 organs (Bura *et al.*, 2016; Low *et al.*, 2021) – knocking or rubbing body parts together as in
29
30 1178 stridulation (Bura *et al.*, 2016; Rosi-Denadai *et al.*, 2018), forced air (Bura *et al.*, 2011; Rosi-
31
32 1179 Denadai *et al.*, 2018), percussion, or tymbalation (Ewing, 1989; Dookie *et al.*, 2017).

33
34
35 1180 Sound created by ‘forced air’ is used across animals. Walnut sphinx (*Amorpha*
36
37 1181 *juglandis*) caterpillars whistle by expelling air *via* muscular contractions through special
38
39 1182 sound-producing spiracles on the A8 abdominal segment (Bura *et al.*, 2011) and can
40
41 1183 successfully deter red-winged blackbirds (*Agelaius phoeniceus*) despite having no further
42
43 1184 defences (Dookie *et al.*, 2017). In the walnut sphinx deimatic sounds are loud, sudden, and of
44
45 1185 longer duration than those produced in other defensive contexts (Low *et al.*, 2021). Other
46
47 1186 caterpillars ‘vocalise’ when attacked, by forcing air out of their gut (Rosi-Denadai *et al.*,
48
49 1187 2018; Bura *et al.*, 2016). Many reptiles including lizards such as the blue-tongued skink
50
51 1188 (*Tiliqua scincoides*) (Badiane *et al.*, 2018) and the frill-necked lizard (*Chlamydosaurus*
52
53 1189 *kingii*) (Perez-Martinez, Riley & Whiting, 2020) also use ‘hissing’ during their deimatic
54
55
56
57
58
59
60

1
2
3 1190 behaviour by forcing air from their lungs across the glottis, but its effect on predator

4
5 1191 behaviour has not been assessed in this context.

6
7 1192 Deimatic behaviour can include stridulation and rasping sounds, for example when

8
9 1193 mantises move their wings and abdomens rhythmically (Hill, 2007; Olofsson *et al.*, 2012b).

10
11 1194 Hill (2007) showed that *Mantis religiosa* have tooth-studded venation on their hindwings and

12
13 1195 denticles on their abdomen and the sound is produced as the former are moved over the latter.

14
15 1196 The peacock butterfly also produces ‘swooshing’ sounds by opening and closing its wings,

16
17 1197 and ultrasonic clicks audible to rodents and bats by a ‘costal clicker’ on the base of the dorsal

18
19 1198 side of the forewing (Møhl & Miller, 1976). Orthoptera also have a wide repertoire of

20
21 1199 defensive stridulatory mechanisms which are performed upon the approach of a predator and

22
23 1200 function to slow or stop its attack (Bedford & Chinnick, 1966; Robinson, 1969; Maldonado,

24
25 1201 1970; Edmunds, 1972). In the katydid *Mygalopsis marki* both adults and nymphs use

26
27 1202 stridulation produced within the head capsule (Bailey & Sandow, 1983). The nymph usually

28
29 1203 attempts to escape by jumping or running but if held in the hand, head stridulation is

30
31 1204 produced.

32
33 1205

34
35 1206 *(c) Olfactory/gustatory components: oozing and regurgitating*

36
37 1207 Chemical defences are typically associated with aposematism, which predators encounter if

38
39 1208 they dare to attempt consumption. They may, however, also appear as components of

40
41 1209 deimatic behaviour which are released when prey perceive a threat from an attacker during

42
43 1210 approach or subjugation, and which can cause predators to slow or stop their attack (Fig. 2).

44
45 1211 Deimatic chemical defences are those released during the behaviour, not those simply present

46
47 1212 in the organism regardless of an attacker’s proximity. That is, deimatic chemical defences are

48
49 1213 produced upon attack.

50
51

52
53

54
55

56
57

58
59
60

1
2
3 1214 Chemical defences may be oozed, frothed, or foamed from joints and glands during
4
5 1215 deimatic behaviour, and may have olfactory and/or visual effects on predator behaviour.
6
7
8 1216 Amphibians exude chemical defences from glands during deimatic behaviour (Ferraro, Topa
9
10 1217 & Hermida, 2013) and defensive posturing can enhance the effect (Williams *et al.*, 2000).
11
12 1218 Fire-bellied toads (*Bombina* spp.) can increase the amount of toxin released through physical
13
14 1219 pressure on the glands when the back is arched (Bajger, 1980; Choi, Lee & Ricklefs, 1999).
15
16
17 1220 During their deimatic behaviour four-eyed frogs (*Physalaemus nattereri*) reveal large black
18
19 1221 discs on their rumps where bradykinin peptides and correspondingly strong signals of related
20
21 1222 gene expression are concentrated (Barbosa *et al.*, 2015). Similarly, many salamanders have
22
23 1223 noxious skin secretions and combine their presentation with various postures to orient the
24
25 1224 glands and associated secretions towards the predator (Brodie, 1977). Mountain katydids
26
27 1225 exude droplets of a bitter secretion from the surface of the abdomen when attacked,
28
29 1226 presumably from glands as yet undescribed, with compounds that originate from their
30
31 1227 preferred diet of *Senecio* daisies (Baker, 2019), such as senecionines and sceneciophyllines.
32
33 1228 Some lepidopterans exude noxious chemicals *via* froth which seems to be deimatic behaviour
34
35 1229 rather than retaliation because they are not shot at the attacker. The saturniid moth *Citheronia*
36
37 1230 *brisottii* is a yellow and orange moth with black intersegmental membranes from which
38
39 1231 newly emerged adult males can expel a tar-like substance (Blest, 1957a). Other lepidopteran
40
41 1232 ‘frothers’ include the arctiine moth *Amerila bubo* which emits a ‘sizzling’ sound from the
42
43 1233 thorax as it produces an odorous froth from two large vesicles, as well as its congener *A.*
44
45 1234 *leucoptera* which displays a bright pink body by spreading its wings and expelling a yellow
46
47 1235 froth from the thorax when disturbed (Carpenter, 1938).
48
49
50
51 1236 Regurgitation is almost ubiquitous among insects when they are attacked, and in
52
53 1237 lepidopteran larvae is also a common accompaniment to acoustic components of deimatic
54
55 1238 behaviour (Bura *et al.*, 2016). Brown, Boettner & Yack (2007) found that defensive
56
57
58
59
60

1
2
3 1239 regurgitation often preceded or accompanied the clicking sounds produced by the
4
5 1240 polyphemus moth (*Antheraea polyphemus*) and was an effective deterrent against predators.
6
7 1241 Similarly, caterpillars of the giant peacock moth (*Saturnia pyri*) produce a chemical secretion
8
9 1242 from integumental bristles when attacked repeatedly while ‘chirping’ (Bura, Fleming &
10
11 1243 Yack, 2009). These examples provide some insight into the chemical components of deimatic
12
13 1244 behaviour but leave many questions unanswered about their proximate mechanisms. In
14
15 1245 particular, it is currently unclear whether both the regurgitation and noise function as a
16
17 1246 deimatic defence, or whether the noises produced are deimatic, and the regurgitation consists
18
19 1247 of toxic secondary plant compounds.
20
21
22
23
24
25

1249 **(3) Changes in deimatic behaviour in response to repeated attack**

1250 Deimatic behaviours can be highly repeatable – performed the same way by the same
1251 individual every time – or can vary among performances. The limited available evidence
1252 suggests variability both within and among individuals. For example, over ‘long’ 24-h
1253 intervals between repeated attacks, consistency in display intensity varied substantially
1254 among individual mountain katydids and were only somewhat repeatable in the magnitude of
1255 their displays (De Bona, White & Umbers, 2020). One explanation may be that performing
1256 deimatic behaviour is condition dependent, but the proximate cause for this variation requires
1257 future research.

1258 Many species increase the intensity of their deimatic behaviour with repeated
1259 exposure to stimuli. In simulated sequential, repeated attacks over short intervals (10 s),
1260 mountain katydids increased the intensity of their display (used more components) (F.
1261 Mourmourakis, S. De Bona & K. D. L. Umbers, unpublished data). Similarly, Brown *et al.*
1262 (2007) investigated the response of clicking polyphemus moth caterpillars to different
1263 numbers of simulated repeated attacks and showed that the number of clicks per individual

1
2
3 1264 increased with attack number. In a different measure, Vallin *et al.* (2005) showed that the
4
5 1265 second time peacock butterflies were approached by a predator, they displayed when the
6
7
8 1266 predator was at a greater distance away than in the first encounter. Increased intensity of
9
10 1267 deimatic behaviour might increase prey survival if displaying maximally upon first stimulus
11
12 1268 carries costs (e.g. conspicuousness) or if the prey are protected from sub-lethal investigative
13
14
15 1269 predator behaviour by a tough exterior, and may also depend on their perceived certainty or
16
17 1270 intensity of danger. The degree to which prey are defended may influence their propensity to
18
19 1271 exhibit deimatic behaviour when repeatedly accosted by potential predators. The chemically
20
21 1272 defended cottonmouth snake reduces its expression of deimatic behaviours with repeated
22
23
24 1273 exposure to human model predators (Glaudas, 2004). However, comparatively less-defended
25
26 1274 juveniles do so to a lesser degree (Glaudas *et al.*, 2006). Predictions around the mechanisms
27
28 1275 underlying prey responses to repeated attacks is fertile ground for future theory and
29
30 1276 experiments.
31
32

33 1277

35 1278 **VII. SURVIVAL VALUE OF DEIMATIC BEHAVIOUR**

37 1279 A limited number of studies have quantified the survival value of deimatic behaviour in the
38
39
40 1280 field and the laboratory with respect to prey survival probability (Table S5) and effects on
41
42 1281 predators (Table S6).
43
44

45 1282

47 1283 **(1) Does deimatic behaviour increase the probability of prey survival?**

49 1284 Ten publications have measured the survival value of deimatic behaviour and/or further
50
51 1285 signals revealed by them using live prey animals, of which eight were laboratory-based and
52
53 1286 two field-based (Table S5). Some prey were putatively profitable, others putatively
54
55 1287 unprofitable (i.e. 'chemically defended'), and most were insects. The efficacy of visual
56
57 1288 components, acoustic components, and their combination have all been investigated. Most
58
59
60

1
2
3 1289 studies did not address whether the experimental predators were natural predators thus
4
5 1290 leaving questions about the ecological and evolutionary significance of the results.
6
7

8 1291
9
10 1292 *(a) Survival value of deimatic behaviour that reveals colour patterns without chemical*
11
12 1293 *defence*
13

14 1294 Vallin *et al.* (2006) examined the effect of the wing-flicking display with eyespots of the
15
16 1295 peacock butterfly against wild-caught blue tits (*Parus caeruleus*). Peacock butterflies, which
17
18 1296 are seemingly palatable to all their known predators, initiated their deimatic behaviour during
19
20 1297 the predator's approach (average 12 cm distance) and all survived ($N = 10$) (Vallin *et al.*,
21
22 1298 2006). Vallin, Jakobsson & Wiklund (2007) found that peacock butterfly visual displays were
23
24 1299 protective against both blue tits and great tits (*Parus major*), in contrast to those of the larger
25
26 1300 hawkmoth *Smerinthus ocellatus*. Both insects had eyespots which were revealed on the
27
28 1301 approach of a predator, however the type of display was different as the hawkmoth *S.*
29
30 1302 *ocellatus* protracted its upper wings to show the eyespots then rocked with its legs, while the
31
32 1303 peacock butterfly continually flicked its wings to hide and reveal its eyespots. Peacock
33
34 1304 butterflies survived 12/12 blue tit attacks and 9/12 great tit attacks whereas only 5/13
35
36 1305 hawkmoths survived blue tit attacks and 1/14 survived great tit attacks. These findings
37
38 1306 suggest that the type of visual display is more important than the presence of eyespots alone.
39
40
41
42
43

44 1307 Mollusc deimatic behaviour can include a combination of posturing and colour
45
46 1308 pattern expression *via* chromatophores without a chemical defence. In a field study, young
47
48 1309 European cuttlefish altered their defensive responses and deimatic behaviour according to
49
50 1310 predator type and avoided attacks (Hanlon & Messenger, 1988). In a laboratory-based study,
51
52 1311 Staudinger *et al.* (2011) showed that longfin squid (*Loligo pealeii*) also alter their defence
53
54 1312 response depending on predator type. Against bluefish (*Pomatomus saltatrix*), a 'pursuit'
55
56 1313 predator, longfin squid primarily used deimatic behaviours, whereas protean behaviours
57
58
59
60

1
2
3 1314 (erratic escape behaviours, *sensu* Edmunds, 1974) were used against summer flounder
4
5 1315 (*Paralichthys dentatus*), an ambush predator. Overall, while deimatic behaviours saved the
6
7 1316 prey's life in 40–64% of interactions, prey were more likely to survive when confronted with
8
9 1317 predators if they fled rather than performed deimatic behaviours (87–92% survival rate). The
10
11 1318 authors suggest that deimatic behaviours are not always the most effective strategy but may
12
13 1319 be employed when prey are unlikely to 'outrun' their predators (Staudinger *et al.*, 2011).
14

15 1320

16
17
18
19 1321 *(b) Survival value of deimatic behaviour that reveals colour patterns with chemical defence*

20
21 1322 Mountain katydids perform deimatic behaviour: they lift their wings to reveal a brightly
22
23 1323 coloured abdomen that exudes a *Senecio*-derived secretion (Umbers & Mappes, 2015; Baker,
24
25 1324 2019; De Bona *et al.*, 2020). Umbers *et al.* (2019) used a field-based experiment to test
26
27 1325 whether the survival value of the katydid's display relates to the prior experience of one of
28
29 1326 their native predators, the Australian magpie (*Gymnorhina tibicen*). In interactions with naïve
30
31 1327 allopatric Australian magpies, katydids survived 70% of encounters, while only 24% of
32
33 1328 katydids survived interactions with sympatric predators. During the experiments katydids
34
35 1329 revealed their display in the subjugation phase of the predation sequence, suggesting that
36
37 1330 camouflage may be their primary defence and that their tough tegmina might help them
38
39 1331 withstand initial predator investigations (Umbers *et al.*, 2019). Katydid were more
40
41 1332 vulnerable to experienced (sympatric) magpies than naïve (allopatric) ones despite the
42
43 1333 katydid's abdominal exudate (Baker, 2019); perhaps they are profitable due to their large size
44
45 1334 (up to 3 g) or perhaps magpies are unaffected by their chemical defence, or both.

46
47
48
49 1335 Brodie *et al.* (1984) investigated the survival value of deimatic behaviour in three

50
51 1336 Asian salamander species, *Paramesotriton chinensis* ($N = 15$), *Paramesotriton*

52
53 1337 *caudopunctatus* ($N = 17$) and *Pachytriton brevipes* ($N = 10$), against short-tailed shrews

54
55 1338 (*Blarina brevicauda*). All three species displayed and survived 100% of encounters despite
56
57
58
59
60

1
2
3 1339 biting and mouthing by shrews (Brodie *et al.*, 1984). Whether shrews were deterred by the
4
5 1340 visual component of the behaviour or by the taste or toxic effect of the exudate is unclear,
6
7
8 1341 and more work is required to determine the selective advantage of each component.
9

10 1342

11
12 1343 *(c) Survival value of deimatic behaviour that reveals sounds*

13
14 1344 Two studies have examined the survival value of the auditory component of deimatic
15
16
17 1345 behaviour in the peacock butterfly by studying a population in the wild during its vulnerable
18
19 1346 over-wintering period (Olofsson *et al.*, 2011, 2012*b*). Hibernating butterflies were placed in
20
21 1347 eight different sites accessible by wild predators and filmed to observe predator–prey
22
23 1348 interactions (Olofsson *et al.*, 2011). Cameras revealed yellow-necked mice (*Apodemus*
24
25 1349 *flavicollis*) and wood mice (*A. sylvaticus*) as the main predators and that the sound of wing-
26
27 1350 flicking displays made predators retreat in 41 out of 52 encounters. Olofsson *et al.* (2012*b*)
28
29 1351 experimentally tested this auditory component against wild-caught mouse predators in a
30
31 1352 laboratory setting. To isolate the auditory component of the display, experiments were
32
33 1353 conducted in dark arenas. In 30 min trials in dark arenas mice were presented with either
34
35 1354 ‘mute’ butterflies which had both ultrasound and stridulatory sound disabled, and ‘sound’
36
37 1355 individuals which were sham-manipulated. 96% of butterflies (23/24) survived the first
38
39 1356 encounter, with no difference in survival between ‘mute’ and ‘sound’ butterflies. However,
40
41 1357 18/24 mice fled when butterflies flicked their wings and fled further from ‘sound’ butterflies
42
43 1358 than from ‘mute’ butterflies. The likelihood of predator-associated wing-flicking behaviour
44
45 1359 varied among individuals. Eight butterflies only required one interaction with mice before
46
47 1360 initiating wing-flicking, while some required up to six interactions or to be physically
48
49 1361 touched. It is not clear whether the sound itself was the deterrent. Olofsson *et al.* (2012*b*)
50
51 1362 suggested that tactile stimulation arising from the sudden movement of air caused by wing-
52
53 1363 flicking or being physically touched by the wings themselves could have deterred the mice.
54
55
56
57
58
59
60

1
2
3 1364 Further, whether the sound is mimetic of a rodent predator, or simply surprising, is unknown
4
5 1365 but would be an interesting avenue for further research.

6
7 1366 Vallin *et al.* (2005) tested the effects of the visual and auditory components in the
8
9 1367 peacock butterfly by presenting various combinations of eyespots and sound to blue tits. No
10
11 1368 difference in survival was found between the sound and no-sound treatments, whereas 33/34
12
13 1369 butterflies with intact eyespots survived the trials, and only 7 of 20 butterflies with covered
14
15 1370 eyespots survived. Taking all the peacock butterfly studies together, eyespots seem to be
16
17 1371 effective against blue tits (Vallin *et al.*, 2005) whereas sound seems to be effective against
18
19 1372 rodents (Olofsson *et al.*, 2011, 2012b). A role of airborne chemical signals was not tested.

20
21 1373 Deimatic behaviour has been studied in detail in a few lepidopteran larvae (Low *et*
22
23 1374 *al.*, 2021). Brown *et al.* (2007) experimentally examined the survival value of mandible
24
25 1375 clicks in the polyphemus moth which are accompanied by regurgitation when the moth is
26
27 1376 grasped by forceps or a beak. In experimental trials, domestic chicks (*Gallus gallus*
28
29 1377 *domesticus*) induced sound production in 100% and regurgitation in 87.5% of larvae ($N = 16$)
30
31 1378 during subjugation and 100% of the caterpillars survived the encounter. Data on long-term
32
33 1379 survival after attack and any sub-lethal effects are needed. The survival value and function of
34
35 1380 walnut sphinx whistles and clicks was tested against yellow warblers (*Setophaga petechia*)
36
37 1381 ($N = 3$) and showed that when caterpillars produced whistles upon attack, the birds hesitated
38
39 1382 and even flew away (Bura *et al.*, 2011). All three caterpillars survived with no visible harm to
40
41 1383 their bodies suggesting potential long-term survival, but to confirm this, a larger sample is
42
43 1384 needed. In simulated attack trials regurgitation in *A. juglandis* was rare (3% of trials)
44
45 1385 suggesting that in nature they may rely on the sound alone.

46
47 1386 Sandow & Bailey (1978) experimentally tested the visual and acoustic components of
48
49 1387 the deimatic behaviour of the sluggish snout-nosed katydid (*Mygalopsis ferruginea*
50
51 1388 (Redtenbacher) syn., *M. pauperculus*) against the salmon-bellied skink, *Ergenia napoleonis*.

1
2
3 1389 Both ‘muted’ katydids ($N = 20$) and intact katydids ($N = 20$) raised their legs, flared their
4
5 1390 mandibles, vibrated their antennae, and attempted stridulation when the predator approached
6
7 1391 (Sandow & Bailey, 1978). Despite both treatments performing stridulation behaviour, only
8
9 1392 intact insects were able to produce a discernible sound. A total of 35 out of 40 katydids
10
11 1393 (87.5%) survived predator encounters and, while there was no difference in survival of
12
13 1394 sound-producing insects compared with muted individuals, the duration of encounters was
14
15 1395 longer for muted katydids (average 4 min) than intact katydids (average 1 min) perhaps
16
17 1396 suggesting that sound production saves the katydid energy by reducing interaction time
18
19 1397 (Sandow & Bailey, 1978).
20
21
22
23
24
25

26 1399 **(2) Does deimatic behaviour actually deter predators?**

27
28 1400 Prey defences should be categorised by the effect they have on predators and, while
29
30 1401 the underlying mechanisms may be unclear, direct measures of predator behaviour can
31
32 1402 indicate survival value (Fenton & Licht, 1990; Skelhorn *et al.*, 2016). We found 17 studies on
33
34 1403 predator behavioural responses to deimatic behaviour on 15 species: five species of mammal
35
36 1404 including three bats and two rodents, and 10 species of bird, all passerines except for
37
38 1405 domestic chicks (Galliformes) (Table S6). Experiments tested predator responses to deimatic
39
40 1406 behaviour that revealed colour patterns (including eyespots) both accompanied and
41
42 1407 unaccompanied by chemical defences, and deimatic behaviours with auditory components
43
44 1408 and no further defences. Fifteen of the 17 studies were laboratory-based studies with small
45
46 1409 sample sizes, two field-based investigations had larger sample sizes. In all studies, predator
47
48 1410 behaviours were either expressly or implicitly considered proxies for a ‘startle response’.
49
50 1411 Qualitative measures of behaviour typically included descriptions of discrete states such as
51
52 1412 ‘wing flap’, ‘hesitation’ (latency to attack), or ‘fleeing’ (increasing the distance between
53
54 1413 themselves and the prey; Table S6). Most studies did not decouple the visual signals revealed
55
56
57
58
59
60

1
2
3 1414 by the deimatic behaviour from the deimatic behaviour itself. Overall, the ways in which
4
5 1415 predator responses have been measured have made direct conclusions about survival value
6
7 1416 difficult to draw and fitness implications difficult to assess.
8
9

10 1417

11
12 1418 *(a) Measures of predator 'startle responses'*

13
14 1419 The 'startle responses' of predators have typically been measured in response to artificial
15
16 1420 prey. Schlenoff (1985) showed that blue jays ($N = 6$) 'startled' in around 50% of their initial
17
18 1421 interactions with models featuring *Catocala*-coloured hindwings (red, orange, and yellow),
19
20 1422 which were revealed when cardboard forewings were removed, but never startled in response
21
22 1423 to models with grey hindwings. The startle response was mostly 'low intensity' ("*dropped*
23
24 1424 *prey model, raised crest, moved in a jerky rapid fashion*"; p. 1059), as opposed to 'high
25
26 1425 intensity', which included the low-intensity behaviours plus flying against the side of the
27
28 1426 cage, emitting an alarm call, and wiping beak. Whether these responses correspond to a
29
30 1427 'startle response', whether they constitute 'slowing' their attack, whether they would protect
31
32 1428 real moths, and what the moths might do in response, is mostly unknown. However, Sargent
33
34 1429 (1973) found that blue jays often released *Catocala* moths when their hindwings became
35
36 1430 exposed during prey handling. They left a beak imprint but did not tear the moth's wings,
37
38 1431 thereby suggesting that exposure of *Catocala* hindwings triggered blue jays to release the
39
40 1432 moths, perhaps involuntarily.

41
42 1433 Dookie *et al.* (2017) showed that the whistling sounds of walnut sphinx moth
43
44 1434 caterpillars 'startled' red-winged blackbirds. Predators experienced a playback of the
45
46 1435 caterpillar's sound in response to contacting a sensor on a feeding dish. The behaviours
47
48 1436 recorded included 'shoulder flinch', 'wing flap', 'ruffle feathers', 'body flinch', 'startle hop',
49
50 1437 and 'fly away'. The number of behaviours recorded was greater for birds that received a
51
52 1438 sound compared to birds that did not (Dookie *et al.*, 2017). An interesting future direction
53
54
55
56
57
58
59
60

1
2
3 1439 would be to compare the responses of birds to control sounds to test if aspects of the
4
5 1440 caterpillar's sounds are especially effective as a deterrent or whether any sound has a similar
6
7
8 1441 effect.

9
10 1442

11
12 1443 *(b) Measures of predator hesitation*

13
14 1444 A long-standing hypothesis about deimatic displays is that they cause predators to pause their
15
16
17 1445 attack for long enough for prey to escape (Ruxton *et al.*, 2004) and latency to attack seems to
18
19 1446 be the response variable most often measured to test this idea. Experiments have usually
20
21 1447 presented artificial stimuli such as sound recordings, computer imagery, and abstract models
22
23 1448 (concentric circles) (Table S6). Of the studies that included experiments on live insects
24
25 1449 (6/17), prey escape behaviour was not described. Vaughan (1983) tested the effect of model
26
27 1450 *Catocala* moth deimatic behaviour on blue jays ($N = 8$) under the hypothesis that the
28
29 1451 anomaly (unexpected), novelty (never previously encountered), and/or rarity (previously
30
31 1452 encountered but uncommon) of moth hindwing colours may cause predators to hesitate.
32
33 1453 Vaughan (1983) showed that novelty can cause blue jays to hesitate in an experiment where
34
35 1454 they interacted with an experimental apparatus consisting of a series of flaps behind each of
36
37 1455 which was hidden colourful discs resembling *Catocala* hindwing colours and mealworms
38
39 1456 (*Tenebrio molitor* larvae). When the jays encountered discs of a colour they had not
40
41 1457 encountered during training, they took longer to eat the reward mealworm than when they
42
43 1458 encountered colours they had experienced before (Vaughan, 1983), and that hesitancy
44
45 1459 increased with colour rarity.

46
47 1460 Using the same apparatus as Vaughan (1983), Ingalls (1993) tested the latency of
48
49 1461 naïve hand-raised blue jays ($N = 8$) to respond to the combined effects of novel colours and
50
51 1462 patterns. She showed that birds took longer to touch discs with novel colours presented in a
52
53 1463 striped pattern with black bands than solid novel colours. Despite potentially confounding
54
55
56
57
58
59
60

1
2
3 1464 order effects, these data suggest that the presence of black bands resulted in the greatest
4
5 1465 latencies compared to discs without black bands as did colour combinations similar to those
6
7
8 1466 found naturally in *Catocala* spp. (Ingalls, 1993). Further, Ingalls (1993) reported interesting
9
10 1467 variation in predator responses, with some birds never habituating to the stimuli and others
11
12 1468 habituating relatively quickly, perhaps suggesting that variability within predator species may
13
14
15 1469 select for variation in prey defences.

16
17 1470 Holmes *et al.* (2018) tested the protective value of deimatic behaviour using
18
19 1471 computer-generated ‘moths’ with and without colourful hindwings that were revealed
20
21 1472 rhythmically at three different speeds to domestic chicks (*Gallus gallus domesticus*). In a
22
23 1473 laboratory setting they showed that rapid movement alone in the absence of conspicuous
24
25 1474 colours delayed a chick’s attack, and that the combination of movement and coloured
26
27 1475 hindwings led to longer latencies. These results suggest that movement alone can increase
28
29 1476 latency in predator responses, that this effect can be enhanced by colourful hindwings and, by
30
31 1477 extension, that movement could precede colour in the evolution of deimatic behaviour.
32
33
34

35 1478

36 37 38 1479 (c) Measures of predators fleeing

39
40 1480 Predators might flee when they experience deimatic behaviour (De Bona *et al.*, 2015).

41
42 1481 Olofsson *et al.* (2012b) showed that when field-caught yellow-necked mice and wood mice
43
44 1482 hear the sound of the peacock butterfly’s display, the majority flee quickly ($N = 18/24$).

45
46 1483 Whether they simply flee or if fleeing is initiated after their startle reflex is released would be
47
48 1484 interesting ground for further testing. Olofsson *et al.* (2012b) also suggested that mice
49
50 1485 respond as they would to a real predator and hypothesised that the peacock butterfly’s sound
51
52 1486 may involve Batesian mimicry of snake hisses (Vane-Wright, 1986; Skelhorn *et al.*, 2016).
53
54

55
56 1487

57 58 1488 (3) Do predator responses change across repeat encounters? 59 60

1
2
3 1489 Changes in predator behaviour across repeated encounters with prey are central to
4
5 1490 understanding the evolution of deimatism. In some environments deimatic prey may be rare
6
7 1491 enough for encounter and re-encounter rates to be very low. However, when repeat
8
9 1492 encounters do occur, predator responses may change depending on encounter rate, predator
10
11 1493 age [younger predators may be more neophobic (Lindstrom, Alatalo & Mappes, 1999;
12
13 1494 Marples & Kelly, 1999) or conservative (Thomas *et al.*, 2003)], variability in deimatic
14
15 1495 behaviours, and whether or how quickly deimatic behaviours are learned and remembered by
16
17 1496 predators.

18
19
20
21 1497
22
23 1498 *(a) Responses to deimatic behaviour that reveals colour patterns with no chemical defences*
24
25 1499 In 12 studies that exposed predators to repeated trials (Table S6), four used prey stimuli with
26
27 1500 colour patterns and no chemical defence. Of those four, two found evidence that predators
28
29 1501 learn to ignore the signals and attack the prey (Vaughan, 1983; Schlenoff, 1985), one showed
30
31 1502 that predators learn to avoid the prey (Ingalls, 1993), and one found no clear pattern (Kang *et*
32
33 1503 *al.*, 2017).

34
35
36
37 1504 Using the *Catocala*-inspired apparatus described above, Vaughan (1983) showed that
38
39 1505 blue jays became habituated to the rarity of colours after the first of four experimental days.
40
41 1506 Initially the latency to attack a rare colour was >200% of that for a common colour, but after
42
43 1507 one day this dropped to ~110% despite the rarity of the rare colour remaining consistent.
44
45 1508 Schlenoff (1985), also using the *Catocala*-inspired apparatus, tested blue jay ($N = 6$)
46
47 1509 responses to different colour patterns. Habituation took 6–25 days for models resembling red-
48
49 1510 banded, yellow-banded and black *Catocala* hindwings and the deterring effect lasted longest
50
51 1511 when trained on two sequential banded patterns rather than a black followed by a banded
52
53 1512 pattern. The flight periods of *Catocala* species last for several weeks, which is enough time
54
55 1513 for predator habituation to hamper the effectiveness of startle displays. Sargent & Hessel
56
57
58
59
60

1
2
3 1514 (1970) observed flight periods exceeding two months for many *Catocala* species in the north-
4
5 1515 eastern USA, and adults can survive for at least 60 days in some species (Gall, 1991).

6
7 1516 With a further seven wild-caught blue jays, Schlenoff (1985) trained them to two
8
9 1517 different forewing types with corresponding hindwings, and found that a startle response
10
11 1518 could be elicited by swapping hindwing colours. She suggested that the anomalous nature of
12
13 1519 the prey's form combined with the striking colour pattern caused the birds to perform startle
14
15 1520 behaviours, not simply that the hindwings colours were unexpected, and that it is unnecessary
16
17 1521 for the patterns to be unknown to the bird. Schlenoff (1985) also showed that encountering an
18
19 1522 unexpected difference in hindwing colour is not enough to elicit a startle response because
20
21 1523 birds trained on *Catocala* patterns do not startle to unexpected grey hindwings.
22
23

24
25 1524 Ingalls (1993) surmised that *Catocala* hindwings may deter blue jays for several
26
27 1525 reasons: (a) they mimic sympatric aposematic species; (b) they are novel; and/or (c) their
28
29 1526 patterns include strong contrasts. She suggested that an optimal number of types of forewings
30
31 1527 must exist. Although an unexpected hindwing colour pattern can deter a predator, if they are
32
33 1528 presented with a new type in every encounter, in theory they could habituate to the rule that
34
35 1529 the hindwing will always be new (Ingalls, 1993). Ingalls' (1993) data suggest that blue jays
36
37 1530 take longer to habituate to startle signals as a function of the diversity of the signals; birds
38
39 1531 presented with a single stimulus colour habituated far more quickly than those presented with
40
41 1532 five colours. However, there was also evidence of consistent individual variation in feeding
42
43 1533 strategy. For example, within a group of birds presented with food associated with five
44
45 1534 different startle colours, two birds habituated after less than 50 trials, while a third was not
46
47 1535 habituated after 149 presentations. This variation in individual predator performance could
48
49 1536 suggest that differences in dietary conservatism (Marples & Kelly, 1999) coupled with
50
51 1537 differences in levels of neophobia could have a significant impact on predator perception of
52
53 1538 defences involving multiple stimuli. Overall, this detailed work on *Catocala* and replica
54
55
56
57
58
59
60

1
2
3 1539 stimuli suggests that colour pattern novelty could be protective but does not provide
4
5 1540 information for responses with real prey. The spatial distribution of hindwing colours in
6
7
8 1541 *Catocala* would merit further study.
9

10 1542

11
12 1543 *(b) Responses to deimatic behaviour that reveals colour patterns with chemical defences*

13
14 1544 Two studies used prey with colour patterns and chemical defences (Kang *et al.*, 2016;

15
16
17 1545 Umbers *et al.*, 2019). Both showed that predators can learn to avoid the prey, while Umbers

18
19 1546 *et al.* (2019) also found that experienced predators can learn to ignore the deimatic behaviour

20
21 1547 and consume the prey. The latter study measured repeated interactions between wild live

22
23 1548 predators and live prey with a deimatic behaviour that reveals a colour pattern and an

24
25 1549 associated chemical defence. Umbers *et al.* (2019) found that Australian magpies naïve

26
27 1550 (allopatric) to mountain katydids learn to avoid them after just one trial, but that experienced

28
29 1551 (sympatric) birds consume katydids at a rate of 50%. This suggests that the initial deterrent

30
31 1552 effect of the display can be lost, perhaps due to the absence of an emetic effect, but the

32
33 1553 conditions that promote repeated sampling of initially repellent prey remain unclear. Using

34
35 1554 chemically defended artificial paper prey, Kang *et al.* (2016) tested whether deimatic

36
37 1555 behaviours facilitate predator avoidance, and in particular whether predators learn to

38
39 1556 associate a cryptic resting appearance with distastefulness. They showed that the speed of

40
41 1557 predator learning was similar between classically aposematic prey and deimatic–aposematic

42
43 1558 prey (Kang *et al.*, 2016).
44
45
46
47
48

49 1559

50
51 1560 *(c) Responses to deimatic behaviour that reveals sounds*

52
53 1561 Three studies investigated predator responses to repeated sound stimuli (Table S6). In two of

54
55 1562 these predators learned to ignore the sound and in the third the result was unclear. Dookie *et*

56
57 1563 *al.* (2017) tested for effects of repeated exposure of red-winged blackbirds to the whistle
58
59
60

1
2
3 1564 emitted by the walnut sphinx caterpillar. They found short-term habituation to the sound
4
5 1565 within each of their two experimental phases but found no difference in habituation between
6
7 1566 phases, indicating that during this two-day period the birds dishabituated despite no changes
8
9 1567 to the experimental set-up (Dookie *et al.*, 2017).
10
11

12 1568

13 14 1569 **VIII. FUTURE DIRECTIONS**

15
16
17 1570 To understand the evolution of deimatic behaviour, further research is required in four broad
18
19 1571 areas: (1) deimatism as part of an antipredator sequence and the need to define antipredator
20
21 1572 ‘space’; (2) quantifying the underlying mechanisms of predator responses to deimatic
22
23 1573 behaviours and how these change with experience; (3) gathering richer data for comparative
24
25 1574 analyses; and (4) ecological patterns of deimatic behaviour. Collaboration across the breadth
26
27 1575 of behavioural sciences while conducting laboratory and field-based experiments and
28
29 1576 including indigenous knowledge will enable advances in this field.
30
31

32
33 1577

34 35 1578 **(1) Deimatism in the antipredator sequence**

36
37 1579 Deimatic behaviour is one part of an antipredator strategy. To understand both the benefits of
38
39 1580 this behaviour and how/when individuals should perform it, we need to establish how it is
40
41 1581 distinct from and interacts with other defensive strategies. The defences that precede and
42
43 1582 follow deimatic behaviour in an antipredator strategy vary among species, among individuals,
44
45 1583 and within individuals. Predators may encounter different sequences of defences when
46
47 1584 encountering different prey (Fig. 2), but equally, prey can, with different degrees of control,
48
49 1585 choose which defences to deploy and when. We predict that the protective value of defences
50
51 1586 can change depending on the combination and order in which they are experienced by
52
53 1587 predators and that recognising, quantifying, and analysing this variation is key to
54
55 1588 understanding the proximate and ultimate aspects of antipredator strategies in general.
56
57
58
59
60

1
2
3 1589 Recognising that antipredator strategies include multiple defences experienced by
4
5
6 1590 predators in a sequence has profound implications (Endler, 1991). It requires us to reframe
7
8 1591 our view of predator–prey interactions as multi-level escalating interactions rather than a
9
10 1592 simplistic single-level signal and response. Therefore, understanding deimatism is
11
12 1593 complicated by how well other defences are defined and the clarity of the conceptual
13
14 1594 boundaries between them. We therefore encourage mapping the full breadth of antipredator
15
16 1595 defences (i.e. antipredator ‘space’) to define these conceptual boundaries (Fig. 2).
17
18
19
20

21
22

23 **(2) Predator responses to deimatic behaviour and prey survival advantage**

24 1598 To arrive at a universally accepted definition of deimatism and establish how it differs from
25
26 1599 other defensive strategies, it is crucial to experimentally demonstrate the proximate causes(s)
27
28 1600 by which deimatism deters predators and to test how these differ from other defences within
29
30 1601 and among attacks and predator individuals. This is needed for predator responses to initial
31
32 1602 and repeat encounters as well as for predators over the course of a single deimatic
33
34 1603 performance. Understanding the mechanisms requires working with ecologically relevant
35
36 1604 predators in natural field settings complemented by controlled laboratory experiments or
37
38 1605 well-designed field experiments to disentangle interacting effects. We need to make careful
39
40 1606 choices about how to measure appropriate behaviours for predator species and assumptions
41
42 1607 as to what these measures represent must be made explicit. Measures that allow us to
43
44 1608 distinguish among proposed mechanisms by which deimatism deters predators are needed.
45
46 1609 They include behaviour, physiology, and the stimuli themselves. A coordinated effort to use
47
48 1610 comparable measurements across studies where possible will allow meta-analyses and
49
50 1611 systematic reviews in the future.
51
52
53

54
55
56 1612 Limited evidence suggests that deimatic behaviours are more effective against naïve
57
58 1613 predators. If this is true, we predict that they should be more common in areas where their
59
60

1
2
3 1614 predators learn slowly, forget quickly, have non-synchronous phenology, or short lifespans
4
5 1615 resulting in a lower frequency of experienced predators. In these cases, predators are unlikely
6
7 1616 to learn or habituate so protection could be maintained even if prey possess no additional
8
9 1617 defences. Interestingly, deimatism might also be favoured where predators learn quickly and
10
11 1618 retain memory efficiently if those traits are associated with reluctance to attack, for example
12
13 1619 when attempting to subjugate dangerous prey. Deimatism unaccompanied by subsequent
14
15 1620 defences should be common, even among populations of predators that are good learners, if
16
17 1621 the phenologies of the prey and predator only overlap for a short time, minimising time for
18
19 1622 learning. Similarly, if deimatism is most effective against naïve predators, it may be more
20
21 1623 common in prey species that are only active when young and naïve predators are more
22
23 1624 common than experienced predators. Deimatism may be rare if predators are long-lived and
24
25 1625 overlap extensively in time with prey.

26
27 1626 If it is true that the protective value of deimatism is directly related to predator
28
29 1627 naïvety, it may allow prey to invade new habitats [e.g. lantern bugs (*Lycorma delicatula*) in
30
31 1628 North America]. Prey species with more effective deimatic displays may expand their
32
33 1629 geographic ranges faster than species without or with inefficient deimatic displays and might
34
35 1630 even displace them. This pattern may be stronger when most predators in the new area are
36
37 1631 naïve. If predators are good learners, then the expanding geographic range may stabilise
38
39 1632 quickly.

40
41
42
43
44
45
46
47 1633

48 1634 **(3) Richer data on prey form and predator response for comparative analyses**

49
50 1635 To understand the evolutionary pathway(s) *via* which deimatism evolves we need to perform
51
52 1636 comparative analyses. However, comprehensive quantitative descriptions of deimatic
53
54 1637 behaviour are currently too rare, most are missing critical measures such as rise time, speed,
55
56 1638 duration, number of components and sensory modes, the qualities of the components
57
58
59
60

1
2
3 1639 (colours, frequencies), whether the behaviour is sustained or includes rhythmical elements
4
5 1640 (*sensu* Blest, 1958), and if and when during the predation sequence the behaviour is
6
7
8 1641 performed. Data on how deimatism differs among life stages, between sexes, and among
9
10 1642 species and higher taxonomic groups are also required.

11
12 1643

13 14 1644 **IX. CONCLUSIONS**

15
16
17 1645 (1) Deimatic behaviour has evolved and been lost multiple times and is widespread across a
18
19 1646 diverse range of taxonomic groups.

20
21 1647 (2) Deimatic behaviours vary greatly in modality, and may be used singly or in combination
22
23 1648 with other defences triggering one or more of the predator's sensory systems.

24
25 1649 (3) Multiple non-exclusive hypotheses have been put forward to suggest the mechanism(s) by
26
27 1650 which deimatic behaviour is protective including the looming reflex, the startle reflex, fear,
28
29 1651 sensory overload, and confusion. Determining whether deimatic behaviours exploit one or
30
31 1652 more of these mechanisms is an area of high priority.

32
33 1653 (4) Deimatic behaviour can be one defence in an antipredator strategy and therefore the
34
35 1654 impact of the display can vary depending on both the predator's physiology and experience,
36
37 1655 and the sequence of defences the prey deploys.

38
39 1656 (5) Limited evidence suggests that deimatic behaviours are more effective against naïve
40
41 1657 predators, which could have implications for range expansion and inter-individual conflict.

42
43 1658 (6) To develop our understanding of deimatic behaviour, further research is required into: (a)
44
45 1659 deimatism as part of an antipredator sequence; (b) quantifying the underlying mechanisms of
46
47 1660 predator responses; (c) comparative analyses; and (d) ecological patterns of deimatic
48
49 1661 behaviour.

34

35 2378
36
37 2379 **Fig. 2.** Five species of insect with their suite of antipredator defences presented together to
38
39 2380 highlight the differences and similarities in their sequences. The phrases below the prey
40
41 2381 represent the signal sent by different defences: ‘I’m dangerous!’ is aposematic; ‘I’m not
42
43 2382 here!’ is camouflage (crypsis or masquerade); ‘Wait!’ is deimatism; ‘I told you so!’ indicates
44
45 2383 that the predator has encountered a bad taste or toxin. The dotted rectangle highlights the
46
47 2384 deimatic component, the defensive phase refers to the order in which the defences are
48
49 2385 deployed or encountered. The predation sequence phase indicates when during the interaction
50
51 2386 the predator typically encounters the given defence (Endler, 1991). The seven-spot ladybird
52
53 2387 represents what is considered classic aposematism, a conspicuous ever-present signal coupled
54
55 2388 with a defence, in this case a chemical defence. Most of the species are camouflaged at rest as
56
57
58
59
60

1
2
3 2389 their primary defence. The walnut sphinx caterpillar represents a deimatic sound, a sound that
4
5 2390 occurs only when a predator approaches or attempts subjugation; the sound acts as a deterrent
6
7
8 2391 but in this case is not coupled with a chemical defence (the sound would still be deimatic
9
10 2392 even if a chemical defence was present; and then would be both deimatic and aposematic).
11
12 2393 The peacock butterfly represents deimatic behaviour that includes a sound and a Batesian
13
14 2394 defence (eyespot). As far as is currently known mantises also fall into this category, as do
15
16
17 2395 cephalopods. The hash symbol on the peacock butterfly's caption 'I'm dangerous?!#' is
18
19 2396 intended to indicate that it is in fact not dangerous; the arrows indicate that the wings open
20
21
22 2397 and close and that this movement is repeated. The mountain katydid reveals its colourful
23
24 2398 abdomen as a predator attempts subjugation and then holds this posture and exudes defensive
25
26 2399 chemicals from the abdomen in a putative aposematic defence. Finally, the spotted
27
28
29 2400 lanternfly's primary defence is aposematism but it too has a deimatic element with the
30
31 2401 opening of its wings to reveal conspicuous colour patterns, followed by a second aposematic
32
33 2402 display as the colours are held exposed. If the lanternfly is consumed, the predator will
34
35 2403 encounter a bad taste and if the predator continues despite the bad taste and swallows the bug,
36
37
38 2404 the predator may regurgitate. Illustrations: Kate Umbers

Table S1. Past descriptions of deimatic displays and terms used to describe the concept. The ‘description’ column provides the relevant passage from the text. The ‘in-text wording’ column provides the name given to the concept as stated by the author.

Citation	Description	In-text wording
Wallace (1889, p. 183)	<i>“Protection by Terrifying Enemies. A considerable number of quite defenceless insects obtains protection from some of their enemies by having acquired a resemblance to dangerous animals, or by some threatening or unusual appearance. This is obtained either by a modification of shape, of habits, of colour, or of all combined.”</i>	Terrifying enemies Threatening or unusual appearance
Poulton (1890, pp. 264, 259)	<i>“terrifying attitude”, “alarming attitude”</i>	Terrifying attitude
Löhner (1919, p. 350)	<i>“Die charakteristischen Eigenschaften des Reflexes sind plötzlicher Eintritt vollständiger Bewegungslosigkeit in stets konstanter Körperhaltung, Muskeltonussteigerung (bei verschiedenen Muskeln in verschiedenem Grade), Lidschluss, Einstellung bzw. Verflachung des Kahluatsspieles und Steigerung der Hautsekretion”</i>	Unkenreflex
Noble (1931, pp. 380–381)	<i>“The typical unken reflex is characterised not only by a distinctive posture and immobility but also by a closure of the eyes, a slowing down of the respiratory movements and an increase in the skin secretion”</i>	Unken reflex

Hingston (1933, p. 3)	<i>“...each one has its mechanism for making it look more threatening when face to face with a rival or enemy. It is the making of these gestures that I call psychological fighting....The working of the mechanism makes the animal look more terrible...”</i>	Psychological fighting
Roonwal (1938, p. 71)	<i>“The purpose of this peculiar attitude ... appears to be to frighten away, by suddenly turning at bay, its natural enemies...”</i>	Frightening attitude
Cott (1940, pp. 213, 232–233)	<i>“Sudden exhibitions of conspicuous colour.” “The sudden appearance of colour previously hidden introduces in itself a new alarming factor which has a psychological effect independent of its mere exhibition.” “The essential character of displays – a sudden and conspicuous exhibition of colour – is achieved by diverse means” “there is essential correlation between the attitude adopted in display and the disposition of the highly pigmented surfaces”, “The conspicuous surfaces are thus normally hidden. Then the changes in appearance ... convert a ... cryptic colour scheme into one that is glaringly conspicuous: the transfiguration is often sudden and rapid; striking and extensive; startling or even terrifying: it occurs typically under special circumstances, namely in times of danger – that is when it is needed; and it is directed in a special manner, namely towards the enemy – that is, where it is needed.”</i>	Intimidating displays

Young (1950, p. 28)	<i>“Many frogs make a sudden exposure of brightly coloured patches on the thighs as they jump. This presumably serves to startle the attacker and such colours may be called dymantic or startling”</i>	Dymantic Startling
Crane (1952, p. 261)	<i>““Startle display” or simply “display”, covers the type of behavior in which tegmina and wings are elevated and special associated motions made in the face of a potential threat. The more usual terms ‘frightening’ or ‘intimidating display’ seem too strong to apply in most of the current instances.”</i>	Startle display
Blest (1957a, p. 257)	<i>“Insects of several Orders possess special protective displays which are elicited by attacking predators, or by stimuli which resemble them”</i>	Protective displays
Hayes (1977, p. 443)	<i>“If immediate escape is not possible, the crayfish assumes: and intensifies a species-specific defensive posture-the predator response posture (PRP). This is apparently the same behavior as exhibited in the ‘Aufbaumreflex’ of crabs ... The PRP protects the individual when shelter is unavailable by defensive presentation of chelae. The initial posture acts as a startle display like those of crabs ... and insects ...”</i>	Predator response postures

Maldonado (1970, p. 61)	<p><i>“Mantids present other remarkable pattern of behaviour: a conspicuous display when they are faced with a ‘threat’. It was called with different names by different authors: the ‘frightening display’ ..., the ‘startle response’ ..., the ‘floral simulation ...’. It will be named the deimatic reaction (DR) (G. δειματώω: I frighten).”</i></p>	<p>Frightening display Startle response Deimatic reaction</p>
Edmunds (1974, p. 150)	<p><i>“When discovered by a predator many animals respond by adopting a characteristic posture which appears to be designed to intimidate the predator... I propose to use the term deimatic behaviour or frightening behaviour to include all such displays postures and frightening noises. Deimatic behaviour produces mutually incompatible tendencies in a predator: it stimulates an attacking predator to withdraw and move away. This results in a period of indecision on the part of the predator (even though it may eventually attack), and this gives the displaying animal an increased chance of escaping...”</i></p>	<p>Deimatic behaviour Frightening behaviour</p>
Schlenoff (1985, p. 1057)	<p><i>“Startle mechanisms involve sudden conspicuous changes in the appearance of behavior of prey which serve to confuse or alarm certain predators.”</i></p>	<p>Deimatic displays, startle responses</p>

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17	Sargent (1990, p. 230)	<i>“There does seem to be agreement that startle is a secondary defense, involving behaviors that a prey organism initiates only after a primary defensive mechanism (usually crypsis) has failed to prevent discovery of disturbance by a predator There also seems to be agreement that the function of a startle display is to interfere in some way with the predator's completion of attack. Beyond this, however, there is considerable confusion as to what constitutes the essential features of a startle display, and why these features are effective in deterring predator attack.”</i>	Startle stimulus / Startle response
18 19 20 21 22 23	Hanlon & Messenger (1996, p. 79)	<i>“Deimatic behaviour is threat, startle, frightening or bluff behaviour and in most cases it serves to make a predator hesitate during the close approach phase of attack”</i>	Deimatic behaviour
24 25 26 27	Kang <i>et al.</i> (2011, p. 709)	<i>“...sudden movements of conspicuous body parts, which elicit startling response in the predator”</i>	Startle effect
28 29 30 31 32 33	Stevens (2013, p. 147)	<i>“Startle displays: These are sudden conspicuous changes in appearance that cause the predator to pause its attack, allowing the prey to escape or conceal itself.”</i>	Startle displays
34 35 36 37 38	Umbers <i>et al.</i> (2015, p. R58)	<i>“...behaviour in which, when under attack, prey suddenly unleash unexpected defences to frighten their predators and stop the attack”</i>	Deimatic displays

Kang <i>et al.</i> (2016, p. 1)	“... a variety of chemically defended insects are rather cryptic when resting, and only in response to predator attacks (post-attack) they perform displays of conspicuous abdomens or hindwings normally hidden under forewings. The function of those displays in unpalatable insects is not well understood. We examined two adaptive hypotheses on this facultative aposematic display...”	Post-attack aposematic display / Facultative aposematic display
Skelhorn <i>et al.</i> (2016, p. e2)	“We propose that we define a deimatic display as any defensive display that causes a predator to misclassify a prey as a potential threat to its immediate safety”	Deimatic display
Umbers & Mappes (2016, p. e7)	“a momentary, transient, conspicuous signal that induces a startle response or overloads the senses of an attacking predator, such that the predator pauses, slows or stops the attack”	Deimatic display
Umbers <i>et al.</i> (2017, p. 1)	“...cause a receiver to recoil reflexively in response to a sudden change in sensory input”, “Crucially, unlike aposematism, reflexive responses to transitory, i.e. deimatic, elements do not require learned or innate aversion.”	Deimatic or ‘startle’ displays
Badiane <i>et al.</i> (2018, p. 104)	“Deimatic display theory is based on a fundamental tenet, that the effectiveness of deimatic displays depends on a sudden transition from an inconspicuous state (e.g. camouflage) to a highly conspicuous display when a predatory attack is imminent, causing a reflexive recoil in the predator ...”	Deimatic display

Holmes <i>et al.</i> (2018, p. 1)	<i>“Deimatic displays, for example, have long been recognised as a discrete form of defence, and are thought to scare or startle predators, or trigger other reflexive responses that cause predators to delay or abandon their attacks”</i>	Deimatism
Ferreira <i>et al.</i> (2019, p. 7)	<i>“Hidden aposematism occur in species that have aposematic color at the axila, underside of the body, tongue, thighs, or post-femoral region. These species usually exhibit the hidden aposematic or deceptive coloration through escape or postures such as rear elevation, unken reflex, and death feigning.”</i>	Hidden aposematism
Ruxton <i>et al.</i> (2019, p. 179)	<i>“Startling signals are secondary defences that occur after the focal prey individual has been singled out for attack”, “Startling signals involve stimulation of the predator’s senses that cause it to delay or break off an attack.”</i>	Startling signals
Loeffler-Henry <i>et al.</i> (2019, p. 3)	<i>“Deimatic display involves the sudden exposure of a hidden signal that induces a startle response or affects predator psychology/behavior in some way to inhibit its attack..”</i>	Hidden contrasting color signals

Table S2. Deimatic behaviours in the context of other similar antipredator defences adapted from Umbers *et al.* (2017).¹Not for movement and conspicuous colour pattern; ²predator must have at least innate aversion of its own predator's eyes; ³not without its model; ⁴predators can learn to ignore the deimatic component, but not the chemical defences.

	Aposematic			Flee	Deimatic		
Antipredator defence:	Aposematism (non-mimic) (resting state)	Müllerian mimicry (resting state)	Batesian mimicry (resting state)	Flash behaviour / protean behaviour	Deimatic behaviour with no further defence	Deimatic behaviour with Batesian mimicry	Deimatic behaviour with aposematism / Müllerian mimicry
Example	Ladybird, poison frogs	Viceroy and monarch butterflies	Snake head caterpillars, butterfly eyespots	Red winged grasshopper <i>Oedipoda germanica</i> , black-tailed jackrabbit <i>Lepus californicus</i>	Giant African mantis <i>Sphrodromantis lineola</i>	Io moths (<i>Automeris</i> spp.), stick insect <i>Ocotophasma martini</i>	Mountain katydid (<i>Acripeza reticulata</i>), spotted lanternfly (<i>Lycorma delicatula</i>), caterpillar with regurgitate
Requires learned or innate aversion	yes	yes	yes	no	no	yes ¹	no
Requires an evolutionary history or environment shared with model species	no	yes	yes	no	no	yes ²	no
Avoidance must be learned from the focal prey species itself	yes	no	no	no	no	no	no
Avoidance can be learned from the focal prey species itself	yes	yes	no ³	no	yes	no	yes
Predators can learn to ignore the display	no	no	yes	yes	yes	yes	no ⁴

Species

Study type

Life stage studied

Primary defence reported

Predator in study

Trigger sensory mode

Predation sequence stage

Display duration description

Display duration (sec) (max if range given)

Movement of large body parts to perform display

Visual aside from movement (colour patch, eyespot, spine, etc.)

Eyespots

Auditory

Olfactory or Gustatory

Elements of display repeated or sustained

Sum of modes (visual modes combined here)

For Review Only

Definition

Source of information

Year of publication

Phylum of displaying animal

Class of displaying animal

Order of displaying animal

Family of displaying animal

Species of displaying animal

Study types categorised into manipulative or description

Stage classified as adult or juvenile

Whether the study described any primary defences (e.g. camouflage)

Species used to trigger display

Method to trigger display

Stage in predation sequence display triggered

Description of display duration

How long the display was held

Whether there was a movement of large body parts to display; 1 = Yes, 0 = No

Whether there was a visual stimulus (except movement); 1 = Yes, 0 = No

Whether eyespots were shown in the display; 1 = Yes, 0 = No

Whether there was an auditory component of the display; 1 = Yes, 0 = No

Whether there as an olfactory or gustatory element to the display; 1 = Yes, 0 = No

Whether there were repeated or sustained elements of the display; 1 = Yes, 0 = No

Sum of sensory modes the display operates in (movement, visual, and eyespots are categorised as on

Table S4. Comparison of the defensive strategies of juvenile and adult life stage

Citation	Order	Species

3 **Aim**

4 To present data on the defence strategies of four genera of salamanders (previously unstudied) and pro

5 To present data on the defence strategies of four genera of salamanders (previously unstudied) and pro

6 To present data on the defence strategies of four genera of salamanders (previously unstudied) and pro

7 To explore the mechanisms and function behind caterpillar clicks. Is clicking an acoustic aposematic si

8 To test whether sound production on its own is enough to induce escape behaviours in predators.

9 To investigate winter predation on hibernating butterflies - are rodents responsible for winter predation

10 To describe the defensive behaviours in the Western Australian katydid and assess the survival value o

11 To evaluate predator-prey interactions between longfin squid, bluefish and flounder: investigate initial

12 To test the efficiency of a generally accepted deimatic display in a natural setting

13 To test the efficiency of a generally accepted deimatic display in an environment in which predators ar

14 To investigate the relative importance of eyespots and sound for defence and the survival value when a

15 To test the hypothesis that different species of butterflies with different defence strategies (e.g. relying

16 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

17 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

18 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

19 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

20 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

21 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

22 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

23 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

24 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

25 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

26 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

27 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

28 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

29 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

30 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

31 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

32 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

33 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

34 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

35 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

36 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

37 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

38 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

39 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

40 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

41 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

42 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

43 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

44 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

45 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

46 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

47 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

48 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

49 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

50 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

51 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

52 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

53 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

54 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

55 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

56 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

57 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

58 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

59 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

60 To test whether large eyespots on lepidopterans are effective for preventing attacks from small birds ar

1
2
3 that have assessed predator responses to deimatic displays

4 **Aim**

5 Do moth clicks function as deimatic displays?

6 Do predators respond differently to butterflies with eyespots compared to the

7
8 How do predators respond to different suddenly presented patterns?

9
10
11 Do eye spots mimic eyes?

12 Do caterpillar whistles function as deimatic displays?

13 Does movement and/or colour patch influence predator response?

14 (1) Does the presence of a banding pattern enhance the startle reaction to noise?

15 Does facultative aposematism differ from crypsis and aposematism?

16 Does size and/or hindwing colour influence predator startle response?

17 Does wing-flicking protect the butterfly from bird or is just conspicuous colour?

18 Do sounds deter mice?

19 Does the presence of eyespots in the startle display influence predator behaviour?

20 Does novelty and/or oddity influence predator startle response?

21 How do moth clicks disrupt bat attack?

22 Does predator familiarity influence the efficacy of startle displays?

23 Is the combination of eyespots and sound more effective than the components alone?

24 Do hind wing patterns deter birds?, Is novelty important?

Treatments

- (1) recorded clicks of an arctiid moth, (2) synthetic clicks (white noise temporally matched to arctiid)
- (1) butterflies with eyespots, (2) butterflies without eyespots
- (1) an equals symbol: '=', (2) a large thin plus symbol: '+', (3) a small thick plus symbol: '+', (4) a single
- (1) an owl with open eyes, (2) an owl with eyes closed, (3) a butterfly with mimetic (real) eyespots, (4) a butterfly with modified (reversed) eyespots, (5) and a butterfly without eyespots
- (1) without sound, (2) with 70 dB sound, (3) with 60 dB sound
- (1) stationary cryptic, (2a, b, c) slow medium and fast dynamic with conspicuous hindwings, (3a, b, c)
- (1) solid-coloured discs, (2) banded discs;
- (1) continuously conspicuous prey, (2) facultatively conspicuous prey, (3) non-conspicuous prey
- (1) large with red hindwings, (2) small with red hindwings, (3) large with grey hindwings, (4) small v
- (1) dead butterflies showing colours, (2) live butterflies cryptic at rest
- (1) butterflies with sound-producers intact, (2) butterflies with sound-producers obliterated
- (1) butterflies with eyespots, (2) butterflies without eyespots
- (1) uniform, pale grey; (2) red and black bands with a narrow white border (redbanded), such as four
- (1) amplifier turned off, (2) amplifier on receiving tape noise, (3) amplifier with recorded moth clicks
- (1) a mountain katydid (2) a palatable orthopteran (3) an inedible greyplasticine ball
- (1) eyespots intact, (2) eyespots obliterated, (3) sound-producers intact, (4) sound producers obliterated
- (1) trained on one colour (2) presented a novel colour
