12 ABSTRACT. Natural and abundant plant triterpenoids are attractive starting materials for the
13
14 synthesis of conformationally rigid and chiral building blocks for functional soft materials. Here
15
16 we report the rational design of three oleanolic acid-triazole-spermine conjugates, containing
17
18 either one or two spermine units in the target molecules, using Cu(I)-catalyzed Huisgen 1,3-
19
20 dipolar cycloaddition reaction. The resulting amphiphile-like molecules **2** and **3**, bearing just one
21
22 spermine unit in the respective molecules, self-assemble into highly entangled fibrous network
23
24 leading to gelation at a concentration as low as 0.5 % in alcoholic solvents. Using step-strain
25
26 rheological measurements, we show rapid self-recovery (up to 96 % of initial storage modulus)
27
28 and sol \leftrightarrow gel transition under several cycles. Interestingly, rheological flow curves reveal
29
30 thixotropic behavior of the gels. To the best of our knowledge this kind of behavior was not
31
32 shown in the literature before, neither for a triterpenoid nor for its derivatives. The conjugate **4**,
33
34 having bolaamphiphile-like structure, was found to be a non-gelator. Our results indicate that the
35
36 position and number of spermine units alter the gelation properties, gel strength, and their self-
37
38 assembly behavior. Preliminary cytotoxicity studies of the target compounds **2–4** in four human
39
40 cancer cell lines suggest that the position and number of spermine units affects the biological
41
42 activity. Our results also encourage exploring other triterpenoids and their derivatives as
43
44 sustainable, renewable and biologically active building blocks for multifunctional soft organic
45
46 nanomaterials.

Introduction

Supramolecular gels resulting from the self-assembly of low molecular mass organic compounds represent an important class of soft materials having their potential in applications in functional materials, catalysis, optoelectronics and sensors.¹⁻⁵ Low molecular weight gelators (LMWGs), undergo hierarchical assembly into highly entangled fibrous networks capable of immobilizing a large number of solvent molecules.⁶ Despite being predominantly comprised of liquids, the resulting gels display solid-like mechanical properties in their rheological behavior.⁷ Importantly, in general molecular organo- and hydrogels offer reversible control of their mechanical properties when perturbed by external stimuli, such as temperature,⁷ light,⁸ electric field,⁹ pH,¹⁰ oxidation-reduction,¹¹ or mechanical stress.¹² The reversible mechanical properties are consequences of the structural reorganization of gelators.⁴ The microscopic changes occurring in molecular gels are attributed to non-covalent intermolecular interactions responsible for the molecular self-assembly. The non-covalent interactions such as hydrogen bonding,¹³ electrostatic effect,¹⁴ hydrophobic effect,¹⁵ London dispersion forces,¹⁶ van der Waals interactions,¹⁷ charge-transfer complexation,¹⁸ metal coordination,¹⁹⁻²¹ halogen bonding,²² and fluorine-fluorine interactions^{23,24} have been explored effectively for designing new gelators. Extensive research, pursued over the last three decades on diverse building blocks, has offered the possibilities towards the rational design of molecular gelators with unique material properties. The building blocks ranging from long chain hydrocarbons,¹⁵ peptides,²⁵ polyaromatics,¹⁸ steroids,²⁶⁻³² carbohydrates,³³ and metal complexes,¹⁹⁻²¹ have been studied extensively. Molecular gels are generally considered as kinetically trapped metastable state, and the gelation process can be controlled by tuning the supramolecular interactions and self-assembly pathways to obtain different material properties.^{34,35} It has been shown that there is a

1
2
3 delicate balance between gelation and crystallization. Therefore, gelation is often considered as
4 failed crystallization.^{36,37} It has been shown that this balance between gel state and the
5
6 crystallization depends on the activation barrier.³⁸
7
8
9

10
11 Molecular gels with a wide range of morphologies including tapes, ribbons, fibers and
12 microcrystalline networks have been reported in the literature.¹⁻⁵ More importantly, self-
13 assembly of chiral gelator molecules has also been shown to exhibit amplification of chirality
14 upon gelation,^{14,39-42} and in some cases formation of helical fibers, twisted tapes or ribbons have
15 been visualized using electron microscopy (EM).^{43,44} Molecular gels also display self-healing
16 and thixotropic behavior making them attractive for industrial, pharmaceutical and cosmetic
17 applications.⁴⁵⁻⁴⁶ Self-healing gels recover their initial properties , e.g., modulus or shape, after

On the other hand, thixotropic gels undergo a transition from gel to solution upon applying stress. However, they recover back to the original gel state when there is no applied shear.^{51,52} According to the IUPAC definition, thixotropy is defined as “*the continuous decrease of viscosity with time when flow is applied to a sample that has been previously at rest, and the subsequent recovery of viscosity when flow is discontinued*”.⁵³ Unlike shear thinning behavior, i.e., decrease in viscosity upon increasing shear stress, thixotropy is a time dependent property. Thixotropic behavior can be studied by time dependent step-strain and rate dependent shear stress *versus* shear rate oscillatory rheological experiments.⁴⁷ Recovery of the gel is observed

1
2
3 after shearing in rate dependent shear stress *versus* shear rate experiment. However, when the gel
4 recovers back to its original modulus, it does not follow the exact path, instead it shows a
5 hysteresis loop, indicating the thixotropic behavior of the gels. The thixotropic properties are
6 generally exhibited by molecular gels composed of the non-crystalline network.⁵⁴⁻⁵⁶ However,
7 there is no specific design strategy available to prepare such gels.⁵⁷
8
9

10
11
12 Irrespective of the nature of the gels and the diversity of building blocks, amphiphilicity has
13 been a common property in a large number of LMWGs.⁵ Furthermore, a certain class of gelators
14 such as cholesterol,²⁷ bile acids,²⁶ plant sterols,⁵⁸⁻⁶² and sorbitol displays varying degree of
15 conformational rigidity, which facilitates a reduction in the entropic losses upon self-
16 assembly.^{63,64} Contrary to other gelators, strong hydrogen bonding interactions are absent in
17 several conformationally rigid gelators, and even if they are present, they contribute to a lesser
18 extent towards self-assembly.⁵ However, in the field of soft materials, plant triterpenoids are a
19 much less explored class of conformationally rigid, naturally abundant, renewable and
20 sustainable resources.⁶⁵ Triterpenoids, being structurally different from steroids, are a class of
21 triterpenes, compounds with 30 carbon atoms, either in linear structure or fused rings, but
22 containing additional heteroatoms or functional groups.⁶⁶ They are precursors for steroids, which
23 compounds, contrary to triterpenoids, are characterized by at least 17 carbon atoms and bear
24 tetracyclic systems with three six-membered rings (A, B and C) and a five-membered ring (D).⁶⁷
25 This class of compounds, including cholesterol (a sterol), and bile acids, has already been
26 extensively studied for their self-assembly and gelation properties.^{1-5,10,26-32}

51 Oleanolic acid [(3 β)-3-hydroxyolean-12-en-28-oic acid, **1**] is a pentacyclic triterpenoid (Figure
52 1) found throughout the plant kingdom in more than 120 plant species, of which especially in
53 *Panax ginseng* root and *Sambucus chinensis* (Chinese elder) in high concentrations.^{68,69} It
54
55
56
57

60

1
2
3 displays a wide range of modest biological activities, including antitumor effects.⁷⁰⁻⁷³ Studies on
4 the self-assembly of triterpenoids have been limited to betulinic acid, arjunolic acid, ursolic acid,
5 glycyrrhetic acid, and oleanolic acid in a few selected organic solvents.⁷⁴⁻⁷⁶ At relatively high
6 concentrations, gelation of oleanolic acid has also been reported in organic solvents.^{74,75}
7
8 Oleanolic acid is a lipophilic compound displaying low bioavailability,⁶⁸ and the functional
9 group chemistry of oleanolic acid has not yet been fully exploited for the synthesis of its
10 derivatives. Therefore, it is desirable to address whether naturally abundant oleanolic acid can be
11 functionalized to obtain amphiphilic building blocks. Such a design requires a careful and
12 selective chemical transformation. Towards this end, naturally occurring sterol-spermine
13 conjugates, such as squalamine, has inspired the synthesis of spermine conjugates of fatty acids
14 and steroids as polycationic amphiphiles.^{77,78} The spermine conjugates have been shown to
15 efficiently bind to DNA, and act as non-viral gene carriers and ionophores.⁷⁹⁻⁸⁴ The synthetic
16 spermine conjugates have been shown to exhibit a broad spectrum of antimicrobial activities,⁸⁵⁻⁸⁷
17 and reported to self-assemble into molecular gels.^{88,89} Previously, the synthesis of different
18 triterpenoid-polyamine conjugates *via* the amide bond formation has been studied and the
19 compounds were subjected to the selected pharmacological screening tests.⁹⁰⁻⁹²

40
41 Herein, we aimed to explore the possibilities to design oleanolic acid-triazole-spermine
42 conjugates as polycationic amphiphiles, to study their self-assembly behavior, potential gelation,
43 morphological features and mechanical properties. To achieve this objective, we have
44 undertaken the following tasks. (a) The Cu(I)-catalyzed Huisgen 1,3-dipolar cycloaddition
45 reaction has been used as one of the key steps to prepare oleanolic acid-triazole-spermine
46 conjugates (Figure 1). Accordingly, three derivatives were prepared by appending spermine
47 conjugates at C(3)-OH (**2**), C(17)-COOH (**3**), and both C(3)-OH and C(17)-COOH (**4**) by

60

1
2
3 selective chemical transformations (Scheme 1). (b) We show that the synthesized conjugates **2**
4 and **3** act as LMWGs when tested in alcoholic solvents, resulting in highly entangled fibrous
5 networks. The VC and VT NMR spectroscopy, IR spectroscopy, X-ray powder diffraction
6 techniques, thermal analysis and electron microscopy were used to investigate supramolecular
7 self-assembly of the target compounds. (c) Using extensive oscillatory rheological measurements
8 and using a visual demonstration, we have shown that the gels exhibit rapid self-healing and
9 thixotropic behavior. (d) Finally, the target compounds **2–4** were subjected to a cytotoxicity
10 screening tests in four cancer cell lines, exhibiting differences in cytotoxicity values that
11 depended on the structure of conjugates.

Experimental section

General

The ^1H and ^{13}C nuclear magnetic resonance (NMR) spectra were recorded on a Bruker AVANCE 600 MHz spectrometer at 600.13 MHz and 150.90 MHz in CDCl_3 or CD_3OD , using tetramethylsilane ($\delta = 0.0$) as internal reference. ^1H NMR spectral data are presented in the following order: chemical shift (δ) expressed in ppm, multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet), coupling constants in Hertz, number of protons. For unambiguous assignment of both ^1H and ^{13}C signals 2D NMR $^1\text{H},^{13}\text{C}$ gHSQC and gHMBC spectra were measured using standard parameters sets and pulse programs delivered by producer of the spectrometer. Infrared spectra (IR) were measured with Nicolet 6700 FT-IR spectrometer (USA) equipped with standard mid-IR source, KBr beam-splitter, DTGS detector and with the cell compartment purged by dry nitrogen during all the measurements. Mass spectra (MS) were measured with a Waters ZMD mass spectrometer in a positive or negative electrospray ionization mode. Optical rotations were measured on an Autopol IV instrument (Rudolph Research Analytical, USA) at 589 nm wavelength, and the values were corrected to 20 °C. All other instruments used in a detailed investigation of supramolecular systems (scanning electron microscopy, transmission electron microscopy, rheometer, X-Ray diffractometer, thermogravimetric analyzer) are described in the Supporting Information. Thin layer chromatography (TLC) was carried out on silica gel plates (Merck 60F₂₅₄) and the visualization was performed using UV detection and by spraying with the methanolic solution of phosphomolybdic acid (5 %) followed by heating. For column chromatography, silica gel 60 (0.063-0.200 mm) from Merck was used. All chemicals and solvents were purchased from regular commercial sources in analytical grade and the solvents were purified by general

1
2
3 methods before use. Oleanolic acid was purchased from Dr. Jan Šarek – Betulinines
4
5 (www.betulinines.com).

11 Procedure for preparation of compound **2**

12 13 14 15 Synthesis of compound **5**

16
17
18 Benzyl bromide (235 μ L, 1.97 mmol) and K_2CO_3 (272 mg, 1.97 mmol) were added to a
19 solution of **1** (600 mg, 1.31 mmol) in DMF (10 mL) in a round bottom flask. The mixture was
20 stirred at r. t. for 17 h. The reaction was monitored using TLC and upon complete conversion of
21 the starting materials to product, the reaction was quenched by adding water to the reaction
22 medium. The reaction mixture was extracted into benzene and washed with brine solution (5 \times
23 50 mL) using a separatory funnel. The organic layer was dried over anhydrous Na_2SO_4 , filtered,
24 and removed under reduced vacuum to obtain the crude product. The crude product was column
25 purified on silica gel using 50/50 v/v (%) petroleum ether/chloroform to 100 % chloroform to
26 afford **5** in a 94 % yield as a white solid.

35
36
37
38
39

40 Synthesis of compound **6**

41
42
43 Sodium hydride (60 % dispersion in mineral oil; 1049 mg, 26.24 mmol) was added to a
44 solution of **5** (896 mg, 1.64 mmol) in dry THF (15 mL) as two portions within 2 h intervals in a
45 round bottom flask. The mixture was stirred at r. t. for 4 h. When the color of the solution turned
46 creamy grey, propargyl bromide (425 μ L, 4.91 mmol) was added to reaction mixture drop by
47 drop under the argon atmosphere. After stirring at r. t. for 5 days, excess sodium hydride was
48 neutralized by slow addition of water. The reaction mixture was extracted to chloroform using a
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 separatory funnel and dried over anhydrous Na₂SO₄. The volatiles were removed under reduced
4
5 pressure. The crude product obtained after aqueous work up was column purified on silica gel
6
7 using 50/50 v/v (%) petroleum ether/chloroform to 100 % chloroform to afford **6** in a 76 % yield
8
9 as a white-yellowish solid.

13 Synthesis of compound **7**

16
17 Compound **15** (529 mg, 1.0 mmol) was added to a stirred solution of **6** (450 mg, 0.77 mmol) in
18
19 DCM (7 mL) in a round bottom flask, followed by CuSO₄·5H₂O/TBTA (1:1) complex solution
20
21 (7.7 mL, 0.39 mmol) and stirred at r. t. for 5 min. To the above mixture, sodium ascorbate (152
22
23 mg, 0.77 mmol) was added, and the contents were mixed at r. t. for 20 h. The reaction mixture
24
25 was then extracted by CHCl₃ and washed with water. After drying the organic layer over
26
27 anhydrous Na₂SO₄, the volatiles were removed under reduced pressure. The crude product
28
29 obtained after aqueous work up was column purified on silica gel using ethanol in chloroform
30
31 [from 100/0 v/v (%) to 100/5 v/v (%)] to afford **7** in a 99 % yield as a white foam.
32
33
34
35

36 Synthesis of compound **8**

39
40 Catalyst (Pd/C (10 %); 550 mg, 0.52 mmol) was added to a solution of **7** (860 mg, 0.77 mmol)
41
42 in a THF/ethanol mixture (10/10 mL). The reaction vessel was repeatedly degassed under
43
44 vacuum and flushed with argon four times. The catalytic hydrogenation was carried out under a
45
46 hydrogen atmosphere at r. t. for 27 h. The reaction mixture was filtered using a sintered glass
47
48 funnel to remove solid. The filtrate was collected and evaporated under reduced pressure to
49
50 furnish white solid that was purified by column chromatography using a gradient mobile phase
51
52 ethanol/chloroform [from 100/0 v/v (%) to 100/2 v/v (%)] to afford **8** in a 90 % yield as a white
53
54

Synthesis of compound **12**

Compound **15** (338 mg, 0.64 mmol) was added to a stirred solution of **11** (142 mg, 0.27 mmol) in DCM, followed by a $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ /TBTA (1:1) complex solution (5.33 mL, 0.27 mmol). After stirring the reaction mixture for five min, sodium ascorbate (105 mg, 0.53 mmol) was added to the mixture and stirred at r. t. for 24 h. It was then extracted into CHCl_3 and washed with brine. After drying the organic layer over anhydrous Na_2SO_4 , the volatiles were removed under reduced pressure. The crude product obtained after aqueous work up was column purified on silica gel using ethanol in chloroform [from 100/1.5 v/v (%) to 100/4.5 v/v (%)] afford **12** in a 96 % yield as a white foam.

Synthesis of compound **4**

A solution of HCl (gas; 1.0 M in ethyl acetate, 37 mL, 36.69 mmol) was added to a solution of **12** (389 mg, 0.25 mmol) and the reaction mixture was stirred at r. t. for 25 h. The resulting residue was filtrated using sintered glass funnel and washed with diethyl ether to furnish **4** as a white solid in a 95 % yield.

Procedure for preparation of compound **15**

Synthesis of compounds **13** and **14**

Sulfuryl chloride (13.5 g, 100 mmol) was added dropwise to an ice-cooled suspension of NaN_3 (6.5 g, 100 mmol) in acetonitrile (100 mL) resulting in a white salt formation (**13**). After stirring the mixture at r. t. overnight, it was cooled over an ice bath, and imidazole (12.9 g, 100 mmol)

1
2
3 was added in portion-wise and the resulting slurry was stirred at r. t. for 3 h. The initial addition
4 of imidazole resulted in pinkish color which turned white upon complete addition. The mixture
5 was diluted with ethyl acetate (200 mL) and H₂O (200 mL), and the aqueous layer was separated
6 and discarded. The organic layer was washed with H₂O (200 mL), then with saturated aqueous
7 NaHCO₃ (2 × 200 mL), dried over MgSO₄ and filtered. The yellow oily liquid **14** obtained after
8 evaporating the solvent was used for the next step without further purification.

Results and discussion

Synthetic procedure

First, we discuss the synthesis of oleanolic acid-triazole-spermine conjugates **2–4** (Scheme 1). To design novel structures, we used Cu(I)-catalyzed Huisgen 1,3-dipolar cycloaddition reaction providing a facile route for 1,2,3-triazoles by selective functionalization of either hydroxyl group [C(3)-OH] or carboxylic acid group [C(17)-COOH].⁹⁵ Apart from the increased yield, the 1,4-disubstituted 1,2,3-triazoles also share certain similarities in their structural as well as physico-chemical properties with the amide bond.^{96,97} The functionalization at C(3)-OH of **1** was achieved by carrying out the benzyl protection of carboxyl acid group and yielded **5**. The compound **5** was then reacted with propargyl bromide in the presence of sodium hydride in THF and **6** was obtained.⁹⁸ Simultaneously, *tert*-butoxy (Boc)-protected azide derivative of spermine derivative **15** was prepared according to the slightly modified literature procedures^{93,94} (see Experimental section and the Scheme S1 in Supporting Information). Compound **6** upon *in situ* generated Cu(I)-catalyzed Huisgen 1,3-dipolar cycloaddition reaction⁹⁸ with **15** in DCM/H₂O at r. t. furnished **7**. Hydrogenation of **7** using 10 % Pd/C as a catalyst under H₂ atmosphere in a THF/EtOH mixture resulted in a deprotection of carboxylic acid, furnishing **8**. Acid hydrolysis of **8** using 1.0 M HCl (gas) in ethyl acetate⁹⁹ resulted in a preparation of **2**. Compound **3** was synthesized by reacting **1** with propargyl bromide in the presence of K₂CO₃ to furnish **9** in the first step. The ester **9** was then subjected to a series of transformation steps that include Cu(I)-catalyzed Huisgen 1,3-dipolar cycloaddition reaction to obtain **10**, followed by a removal of the Boc-protecting groups using 1.0 M HCl (gas) in ethyl acetate to get the conjugate **3**. To synthesize **4**, the intermediate **9** was reacted with propargyl bromide in the presence of sodium hydride to obtain **11**. Subsequently, Cu(I)-catalyzed Huisgen 1,3-dipolar cycloaddition reaction

1
2
3 was applied under the above described conditions, yielding **12**. A removal of the Boc-protecting
4 groups, present in **12**, was carried out by 1.0 M HCl (gas) in ethyl acetate, furnishing **4**. A
5
6 detailed synthetic and purification procedures are described in the Experimental section. The

12 are presented in Supporting Information (see also Figures S3-S15).
13
14
15

16 17 18 Gelation studies 19

20
21 The presence of the lipophilic core and the cationic spermine side chains impart amphiphilic
22 nature to the conjugates **2** and **3**. The oleanolic acid core has an end to end length of 1.45 nm
23 based on its solid-state structure, and the triazole linked spermine in its fully stretched
24 conformation has a length of 1.97 nm (Figure 1 and Figure S1). Though **2** and **3** have a similar
25 overall structure, they differ in the position of spermine substituents, i.e., they are positional
26 isomers. The conjugate **2** has a free carboxylic acid group, whereas **3** has a free hydroxyl group.
27
28 On the other hand, **4** has both these groups functionalized, resulting in a bolaamphiphile-like
29 molecule. More importantly, oleanolic acid-triazole-spermine conjugates **2–4** differ from
30 conventional surfactant molecules due to the conformationally rigid and chiral triterpenoid core.
31
32 Natural bile salts (steroid compounds) and their synthetic derivatives are classical examples for
33 this type of unconventional surfactants and are known for their unique aggregation behavior.²⁶⁻³²
34
35 Depending on the number and position of hydroxyl groups and functional transformation, bile
36 salts and their derivatives are known to form globules, tubules, and fibrous gel networks.^{10,26-32}
37
38 Therefore, it is desirable to investigate the self-assembly behavior of the novel amphiphilic
39 building blocks based on the plant triterpenoid **1**. The solubility of **2–4** was tested in 23 different
40 solvents (Table 1). Interestingly, **2** and **3** underwent gelation – mostly in polar protic solvents –

when tested at 1.0 % (note: from hereafter all percent values (%) are in w/v of gelator/solvent), as suggested by vial inversion test (we have used 1.0 % as an upper limit for gelation tests). Conjugate **2** was gelled at a concentration as low as 0.5 % in 1-butanol, and 1.0 % in 1-propanol, 2-propanol, 1-pentanol, 1-hexanol, 1-heptanol, and in polar aprotic solvents, pyridine and *N,N*-dimethylformamide (DMF). Similarly, gels were obtained for **3** in 2-propanol, 1-butanol, 1-pentanol, 1-heptanol, in polar aprotic solvents, pyridine, DMF, acetonitrile, and, surprisingly, in a non-polar solvent (1,4-dioxane) at a concentration of 1.0 %. The resulting gels were translucent or opaque, depending on the concentration and the type of organic solvent used for gelation (Figure 2). In all other tested organic solvents, both **2** and **3** remained in the solutions or precipitated after allowing to stand at r. t., or they remained insoluble (Table 1). However, **4** is either insoluble or remaining in a solution, no gelation was observed. This finding already suggests that the gelation is strongly affected by the number and position of the spermine units, as well as by the presence of the unconjugated hydroxyl or carboxylic acid groups. Driving force of the gel formation is connected with the presence of electrostatic interactions between a quaternary amino group present in the spermine chain and a chloride anion,⁶¹ which is present in all three conjugates. However, intermolecular hydrogen bonds between the carbonyl and the amino groups represent an important factor when non-gelator property of **4** is taken into consideration in contrary to those of **2** and **3**.

Table 1. Solvents (non-polar, polar protic, polar aprotic, acid and bases) tested for gelation studies of **1–4** (gelation concentration $c = 1.0$ %).

Electron microscopy analysis

Scanning electron microscopy (SEM)

To investigate the structure of the supramolecular assemblies, we carried out EM (SEM or TEM) imaging of all the studied gels of **2** and **3** (Note: only representative micrographs are presented in main text). Ambient drying of gels (xerogels) resulted in film-like structures due to drying artifacts (Figure S16). Therefore, aerogels were prepared using liquid nitrogen freeze-drying technique (see Supporting Information for details). The SEM image of methanol gel of **1** (Figure 2a) showed microcrystalline structures (Figure 2). A representative SEM image of 0.5 % 1-butanol gel of **2** is shown in Figure 2e, displaying highly entangled fibrous networks with an average lateral dimension of 35 ± 5 nm and with indefinite length. To study the effect of concentration on morphology, SEM micrographs of 1-butanol gels of **2** at four different concentrations (0.5, 1.0, 1.5 and 2.0 %) were obtained (see Supporting Information, Figure S17). However, the fiber diameter changed slightly upon increasing the concentration, and, the fibers tend to be densely packed, (see Supporting Information, Figure S18, and Table S2), a property, that is consistent with the literature reports.¹⁰⁰ Moreover, for gels at higher concentrations, due to dense packing the determination of the lateral dimensions of individual fibers was challenging. In all the solvents tested for gelation, **2** showed similar morphological features with highly entangled network of fibers (Figure S16). A representative SEM micrograph from the 1,4-dioxane gel (1.0 %) of **3** with highly entangled fibrous networks is shown in Figure 2f. The fiber morphologies in aerogels of **3** are similar to those of **2**. However, the lateral dimensions of the fibers were different from those for **2**. For example, aerogels derived from DMF gels of **2** and **3** showed the lateral dimensions of 43 ± 5 nm and 29 ± 5 nm, respectively (see Supporting Information, Figure S19 and Table S3).

Figure 2. Gelation and scanning electron microscopy. Electron micrographs of representative gels a) **1** in methanol, 1.0 %, b) **2** and **3** in different solvents, 1.0 %, c) **2** in 1-butanol at different concentrations; d) SEM micrographs of methanol gel of **1**; e) SEM micrograph of freeze-dried 1-butanol gel of **2**, 0.5 %, and f) SEM micrograph of freeze-dried 1,4-dioxane gel of **3**, 1.0 %.

Transmission electron microscopy (TEM)

To obtain more information about fiber morphology, TEM imaging was performed for all gels (see Supporting Information for sample preparation). TEM micrographs of all the gels studied in this work showed the presence of fibrous networks. Figure 3 shows the representative TEM micrographs of 1-propanol gel of **2** (1.0 %) and 1-pentanol gel of **3** (1.0 %). More importantly, in some cases, the helical twist was observed (Figure 3b, 3d) with a pitch length of about 90 nm and lateral dimension varying from 15 to 25 nm (Figure 3e). The lateral dimensions observed under TEM imaging are comparable with the results obtained from SEM imaging. The TEM micrographs from all other gels are presented in Supporting Information (Figure S20).

Figure 3. Transmission electron microscopy. a,b) TEM micrographs of 1.0 % 1-propanol gel of **2**; c,d) TEM micrographs of 1.0 % 1-pentanol gel of **3**; e) a single fiber with helical twist is shown (left) together with its graphical representation (right).

X-ray powder diffraction and thermal analysis

To further gain insights about solid state and thermal properties of the conjugates, thermogravimetric analysis (TGA), differential scanning calorimetry (DSC) and X-ray powder diffraction (XRPD) studies of oleanolic acid (**1**), synthetic solid compounds **2–4**, but aerogels from 1-butanol gel of **2** (1.0 %) and 1-pentanol gel of **3** (1.0 %) were performed (see Supporting

1
2
3 Information for experimental details and results). TGA and DSC results revealed a decreased
4 decomposition temperature for the conjugates and the aerogels compared to parent **1** (see
5 Supporting Information, Table S4, Figures S21, S22). XRPD studies revealed the semi-
6 crystalline nature of **1**. However, the target conjugates **2–4** showed broad featureless patterns in
7 their powder X-ray patterns (see Supporting Information, Figure S23). These results suggest that
8 the synthetic solids as well as the self-assembled nanostructures in gels are amorphous.

18 Mechanical properties of gels

19
20
21 For rheological measurements, only those gels that are suitable for repeated rheological
22 measurements were used that can be transferred onto the rheometer without losing their
23 structures. Accordingly, pre-made and stabilized 1-propanol, 2-propanol, 1-butanol and 1-
24 heptanol gels of **2** were studied (Figure 4, see also Supporting Information for Experimental
25 details). The gels have already shown that the storage modulus (G') is several folds higher than
26 that of loss modulus (G'') suggesting that the systems under investigation are already in gel state
27 (viscoelastic) and remained constant under time sweep (30 min) experiments (Figure 4a). The
28 storage modulus (G') of gels varies as a function of the frequency under frequency sweep
29 experiment (Figure 4b). The frequency sweep experiment provides insights into the nature and
30 lifetime of the bonds that are involved in network junctions.¹⁰¹ The frequency dependence of the
31 storage and elastic moduli observed for gels derived from **2** and **3** indicates the presence of
32 junction networks and temporary bonds that form the networks. Such temporary bonds are
33 sensitive to the frequency of the mechanical stress and the lifetime of the bonds. Our results
34 suggest that there are junction networks as supported by SEM and TEM micrographs (Figures 2
35 and 3). At a given concentration the stiffness of the gels varied in the following order, 1-butanol
36 > 1-propanol > 2-propanol > 1-heptanol with G' values of 1.4 kPa, 0.7 kPa, 0.5 kPa, and 0.025

59
60

1
2
3 kPa, respectively (see Supporting Information, Figure S24c1). For a given solvent, the modulus
4
5 was increased as a function of concentration, a property that is typical for low molecular weight
6
7 gelators. Figure 4e, 4f shows the concentration dependent, stress and strain sweep experiments
8
9 for 1-butanol gels of **2** (for time and frequency sweep experiments see Supporting Information,
10
11 Figure S24a, S24b). For 1-butanol gels of **2**, the storage modulus was increased from 0.22 kPa
12
13 for 0.5 % to 6.5 kPa for 2.0 %, which is a 30-fold increase in the stiffness (see Supporting
14
15 Information, Figure S24c2). Yield stress values were determined by tangent analysis method.
16
17 The yield stress values of 1-butanol, 1-propanol, 2-propanol, and 1-heptanol gels of **2** were found
18
19 to be 30, 24, 13 and 8 Pa, respectively (Figure 4c). Similarly, yield stress values for 1-butanol
20
21 gels of **2** at different concentrations were determined as 3, 16, 40 and 95 Pa for 0.5, 1.0, 1.5 and
22
23 2.0 %, respectively (Figure 4f). For compound **3**, gels that are suitable for rheological
24
25 measurements were obtained from 1-pentanol and 1-heptanol. Time, frequency, strain, and stress
26
27 sweep experiments were performed for 1-heptanol and 1-pentanol gels of **3** and the details are
28
29 presented in Supporting Information, Figure S24. For 1.0 % gels, G' values were found to be 1.4
30
31 kPa and 0.3 kPa for 1-pentanol and 1-heptanol, respectively. The only common solvent for
32
33 rheological measurements of **2** and **3** was 1-heptanol, in which both compounds formed gel that
34
35 could be transferred onto the rheometer without losing its structure. The storage modulus of 1.0
36
37 % 1-heptanol gel was found to be 0.025 kPa (for **2**), and 0.95 kPa (for **3**), respectively (see
38
39 Supporting Information, Figure S24c1, S24d). The yield stress values of 1-pentanol and 1-
40
41 heptanol gels of **3** were found to be 51 Pa and 35 Pa, respectively (see Supporting Information,
42
43 Figure S24f). These results show us that **2** forms stronger gel than **3** in alcoholic solvents, in
44
45 general. Furthermore, the stiffness of gels decreases with increasing number of carbon atoms in
46
47 the alcoholic solvents. The structure of these carbon chains present in alcoholic solvents, i.e.,
48
49
50
51
52
53
54
55
56
57
58
59
60

whether they are branched or linear, has also an impact on stiffness of gels. Linear chains-bearing alcoholic solvents seem to form more stiffed gels than the alcoholic solvents with branched carbon chains. Therefore, to induce gelation, a delicate balance exists between carbon chain length and its structural property in the used alcohols.

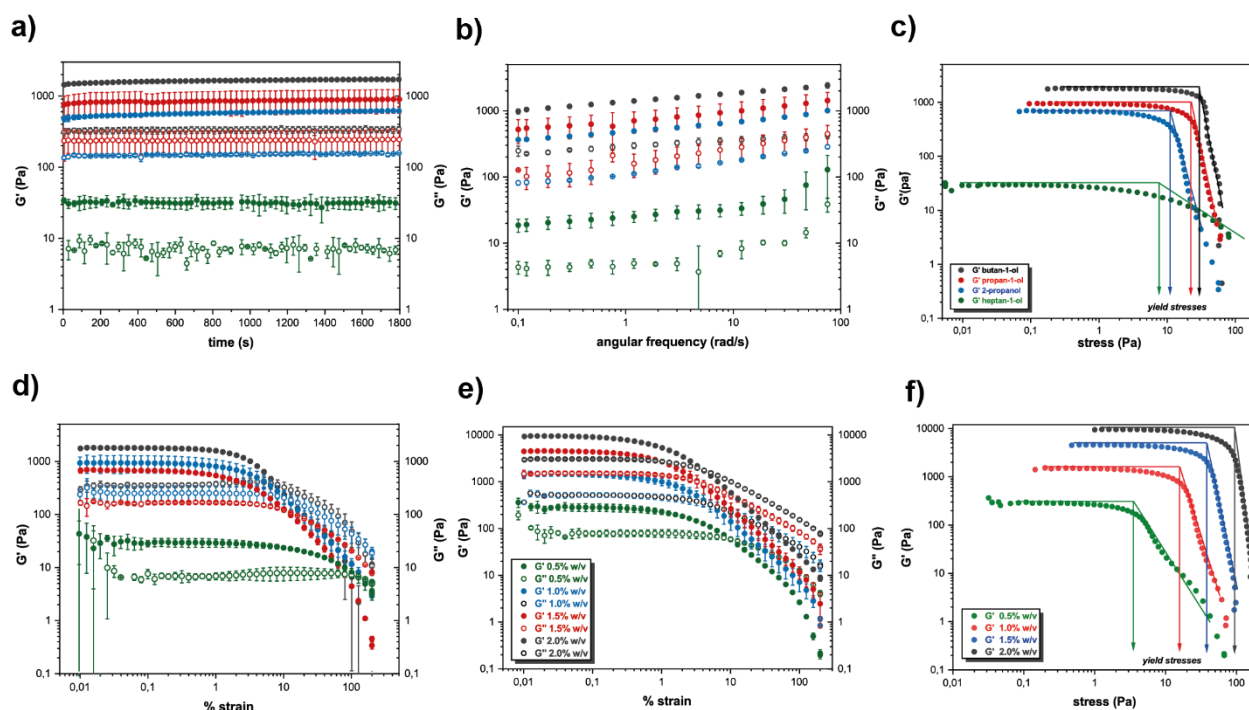

Figure 4. Rheological properties of gels. a) Time sweep experiments of gels derived from **2**, b) frequency sweep experiments of gels derived from **2**, c) stress sweep experiments derived from **2**, d) strain sweep experiments derived from **2** [(full circles indicate G' , empty circles indicate G'' , 1-butanol gel (black), 1-propanol gel (red), 2-propanol gel (blue), 1-heptanol gel (green)], e),f) the effect of concentration on mechanical properties of 1-butanol gel of **2**.

Self-healing properties

Step-strain rheological measurements were performed to investigate the reversible gel \leftrightarrow sol transition and self-recovery, under several cycles. For the step-strain experiments, controlled

1
2
3 strains of 0.1 % and 150 % were applied for 60 s, respectively. The gels showed an immediate
4 response to increased strain by turning into sol indicated by the rapid decrease in G' by several
5 folds and well below that of G'' (Figure 5a). The application of increased strain also appears to
6 break the structure further during the 60 s experiment as shown by the gradually decreasing
7 elastic moduli values in the subsequent cycles. The gels recovered their original mechanical
8 strength almost instantaneously upon switching to lower strain (0.1 %) i.e. rapid self-recovery.
9
10 Importantly, the process can be repeated for several cycles. However, slightly lower G' was
11 observed after the first high–low strain cycle, which remained constant in subsequent cycles, a
12 property typically observed for several low molecular weight gelators. Importantly, the gels were
13 able to recover up to 96 % of their original storage moduli even after four cycles. The percentage
14 recovery of storage moduli of 1-butanol, 1-propanol, and 2-propanol gels of **2** was found to be
15 96, 89 and 78 %, respectively (Figure 5a, see also Supporting Information and Figure S25 for
16 other gels of **2** and **3**). Similarly, for 1-pentanol and 1-heptanol gels of **3**, the percentage recovery
17 of the original storage moduli was found to be 76 and 75 %, respectively.

40 Thixotropic properties

41
42
43 To evaluate the thixotropic property of gels of **2** and **3**, their flow curves were also measured
44 (Figure 5b, 5c). The measurement was carried out as follows: the shear stress was measured
45 while increasing the shear rate from 0 to 100 s^{-1} and then decreased back to 0 s^{-1} . Figure 5b and
46 5c shows change in the viscosity and shear stress as a function of shear rate for 2-propanol gel
47 (1.0 %) of **2** and 1-pentanol gel (1.0 %) of **3**, respectively. A clear hysteresis loop showing a
48 clockwise turn was observed suggesting the gels under investigation display thixotropic property.

59
60

At macroscopic level, by manual shaking, the gel resulted in a gel \leftrightarrow sol transition recovering within 60 seconds, showing a rapid recovery. Figure 5d and 5e shows selected snapshots of 1-butanol gel (1.0 %) of **2**, demonstrating a rapid recovery and thixotropic properties by either shaking or vortexing (see video S1). Thixotropic nature of gels can be explained on the basis of the amorphous fibrous network. X-ray diffraction studies of the aerogels suggest the amorphous nature of the gel network (Figure S23). This observation is in agreement with other thixotropic gels reported in the literature.⁵⁴⁻⁵⁶

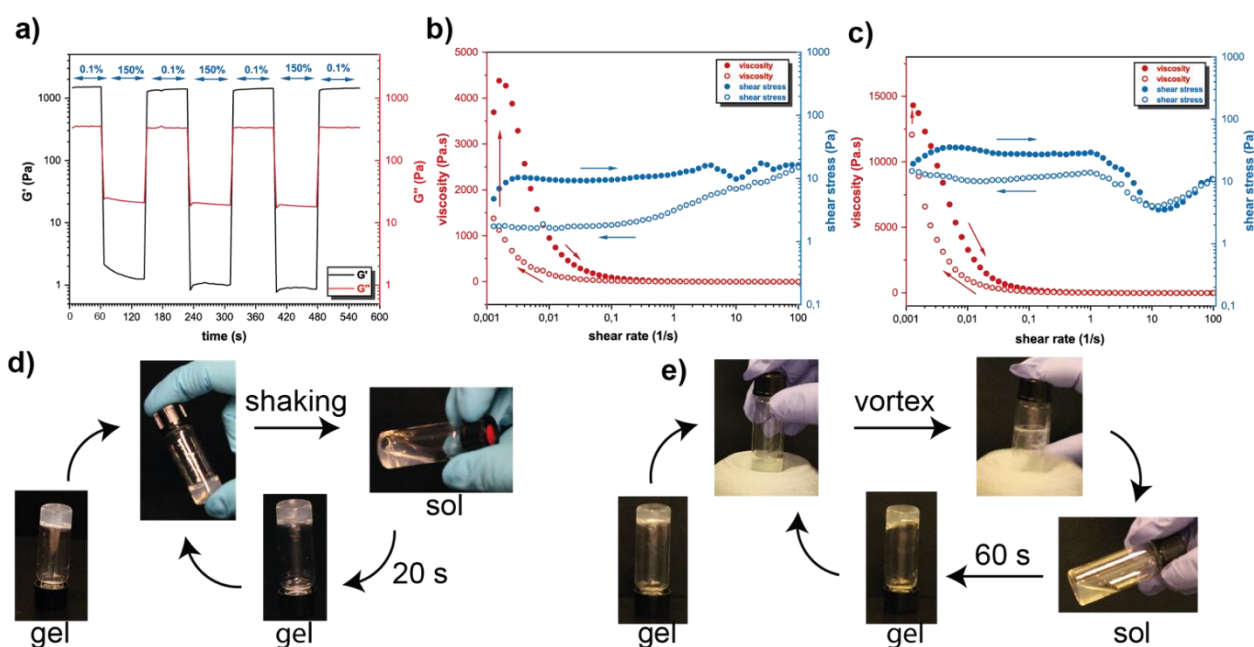

Figure 5. Self-recovery and thixotropic properties. a) Step-strain experiments showing self-healing properties of 1-butanol gel of **2**, flow tests showing viscosity v/s shear rate and shear stress v/s shear rate for b) 2-propanol gel of **2** and c) for 1-pentanol gel of **3**, d, e) snapshots from video demonstrating thixotropy by manual shaking and vortexing of 1-butanol gel of **2**.

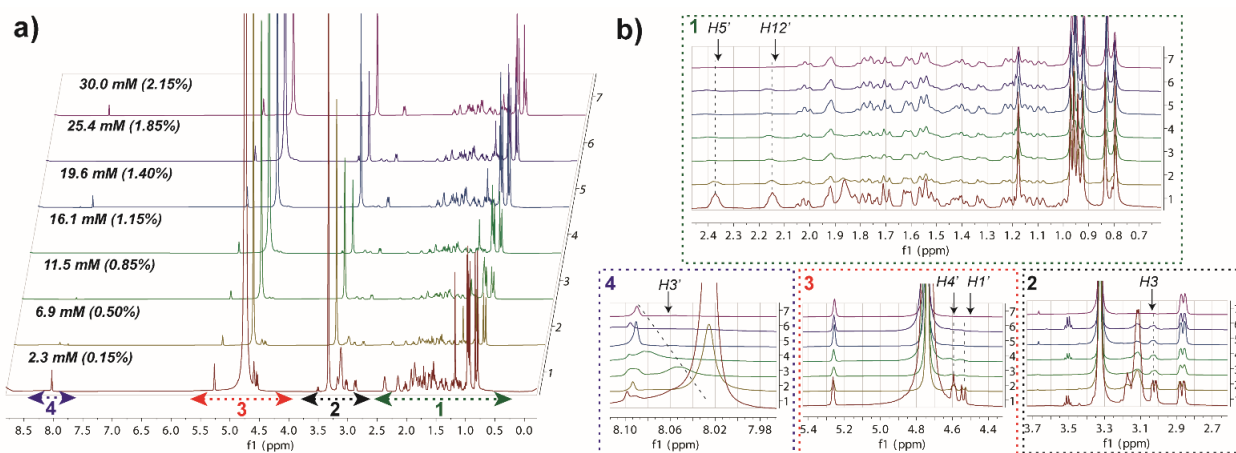

Figure 6. VC ¹H-NMR graph of a) **2** in CD₃OD at 40°C, b) expanded version of VC ¹H-NMR graph of **2** in 4 different regions (right).

VC and VT ¹H NMR

The VC ¹H NMR spectra of **2–4** in CD₃OD at 40°C (to mimic the conditions of gel preparation) were measured to gain insights into the interactions involved in self-assembly. The reason why CD₃OD was chosen for the VC ¹H-NMR spectra measurements was the observation of a gel even at a concentration as low as 0.5 % in the NMR tube when used other solvents than CD₃OD, e.g., DMF. Because **2** and **3** form gels mostly in alcoholic solvents, this finding prompted us to check their behavior in CD₃OD. Relatively sharp ¹H NMR resonance peaks, which arise presumably from the non-aggregated molecules, were observed at a low concentration for **2–4**. As the concentration increased, the peaks turned to become broader or even remained NMR silent with a slight downfield shift. The broadening, along with the invisible nature of certain signals is possibly due to a self-assembly of **2–4**. Figure 6 shows the VC ¹H NMR spectrum in a concentration range from 0.15 % to 2.15 % of **2** (see Supporting

1
2
3 Information, Figure S26 for **3** and **4**). The signal broadening is more pronounced for **2** compared
4
5 to that of **3** and **4**. The fact that certain NMR signals turned to become NMR silent above certain
6
7 concentration is attributed to the large size of the aggregates. The VT ^1H NMR spectra of **2–4**
8
9 were also measured to see the effect of temperature on aggregates. However, the maximal
10
11 temperature limit of 40 °C can be reached when CD_3OD used as an NMR solvent, due to its
12
13 boiling point. As a consequence of this maximum temperature limitation, the ^1H NMR
14
15 experiments carried out accordingly, revealed no important information about aggregates. In
16
17 other words, no changes in the chemical shift values of the ^1H NMR resonance peaks were
18
19 observed (see Supporting Information, Figure S27).
20
21
22
23

24 IR spectroscopy

25
26
27
28 Inter- and intramolecular interactions can be investigated using IR spectroscopy, which is
29
30 frequently used technique in gel studies. With the aim to better understand the driving forces
31
32 leading to the gel formation, IR spectra of the aerogels prepared from **2** and **3** in different
33
34 solvents were measured. The spectra of aerogels were compared with those of the corresponding
35
36 synthetic solids in their powder form (see Supporting Information, Figure S28). The IR spectra
37
38 of the aerogels, as well as those of the synthetic solids exhibited similar characteristic peaks.
39
40 This finding suggests that the molecular structure in the gel state resembles that of the synthetic
41
42 powder form. These findings are in agreement with the XRD results. In addition, no spectral
43
44 differences were observed in the IR spectra when aerogels, prepared in different solvents, were
45
46 compared. This result is in agreement with the SEM and TEM micrographs, in which similar
47
48 entangled fibrous networks were obtained in each solvent used for the gels preparation. This type
49
50 of observation has already been described for steroidal gelators in the literature,⁵⁸ however, it is a
51
52 novel knowledge found with the triterpenoid-based gelators described here.

Cytotoxicity

The target compounds **2–4** showed cytotoxicity in the four tested cancer cell lines (Table 2; for experimental details See Supporting Information). CDDP (cisplatin) was used as a positive reference compound. An important difference was observed in the cytotoxicity values of **2** in comparison with those of **3** and **4**. It seems that the location and number of the spermine units on the triterpenoid skeleton plays a key role for cytotoxicity. Substitution of the C(17)-COOH group with the spermine substituent in **3** (C(3)-OH group remains free) and in **4** led to the one order increase of cytotoxicity in comparison with the data obtained for **2**. Surprisingly, high cytotoxicity was found in tests of **4** in malignant melanoma cells (G-361). Melanoma cancer belongs among the most aggressive cancer types. Even though **3–4** were toxic towards human fibroblasts, they still exhibited better cytotoxicity profile than CDDP (a positive control) against several cancer cell lines (**3** against MCF7 and HeLa, and **4** against MCF7, HeLa and G-361).

Table 2. Cytotoxicity (IC₅₀ [μM]) of **2–4** in four cancer cell lines and normal human fibroblasts after 72 h.

Compound	MW	Cytotoxicity (IC ₅₀ [μM]; 72 h)				
		CEM	MCF7	HeLa	G-361	BJ
2	723	29.8 ± 3.3	28.0 ± 1.0	12.6 ± 2.8	27.8 ± 0.9	14.2 ± 0.4
3	723	2.1 ± 0.8	3.7 ± 1.0	3.7 ± 0.5	6.6 ± 0.4	2.3 ± 0.1
4	989	7.1 ± 1.1	2.7 ± 0.7	2.2 ± 0.1	0.8 ± 0.0	1.9 ± 0.0
CDDP ^a	300.05	0.8 ± 0.1	7.7 ± 1.7	11.4 ± 3.8	4.5 ± 0.6	6.9 ± 0.9

^a *cis*-Diamminedichloridoplatinum(II) (cisplatin), a pharmacologically used agent for treating different cancer types, a positive reference compound.

Conclusion

Our results showed that modifications of triterpenoids allow the rational design of novel building blocks with unique self-assembly and material properties. The synthetic approach presented here supports that Cu(I)-catalyzed Huisgen 1,3-dipolar cycloaddition represents a convenient synthetic method for the facile chemical transformation of sterically hindered functional groups of triterpenoids. In this study compounds **2–4** were synthesized starting from **1** and their structure was characterized. Conjugates **2** and **3** exhibited solvent dependent self-assembly resulting in thixotropic and self-healing organogels with helical fibrous networks. Gelation properties of the studied compounds were affected by the position and the number of the spermine units. Bolaamphiphile-like compound **4** was found to be a non-gelator, and displayed different behavior than **2** and **3** that were found to be gelators. Gels obtained from **2** and **3** exhibited different stiffness values. Our results suggest that the structural modification of gelator and the solvents significantly affect gelation and mechanical properties of gels. The gels, xerogels and aerogels, were characterized using multiple and complimentary microscopic and spectroscopic methods. Further, mechanical property of gels was extensively studied using oscillatory rheological measurements.

Cytotoxicity of **2–4** was tested in four different cancer cell lines within this investigation. The cytotoxicity depends on the way of substitution of the oleanolic acid with the spermine side chains. Importantly, compounds bearing spermine as a substituent in the C(17)-COOH group, i.e., **3** and **4**, showed higher cytotoxicity. Furthermore, **3** (against MCF7 and HeLa) and **4** (against MCF7, HeLa and G-361) showed somewhat improved cytotoxicity profile compared to that of positive control CDDP.

1
2
3 Overall, this work shows that there is a potential to utilize naturally abundant sustainable
4 oleonic acid for new functional materials, and this approach can be extended to other
5 triterpenoids. More importantly, this work also opens possibilities to theoretical and
6 computational chemists to investigate the self-assembly of this new class of amphiphiles. Each
7 partial investigation in this work contributed to a formation of a complex view on characteristics
8 of the studied supramolecular systems with the ability to form supramolecular gels exhibiting a
9 potential to become promising next-generation materials for a broad range of technical and
10 biomedical applications.

ACKNOWLEDGMENT

The authors thank for funding of this research through the grants from MPO: FV10599 (Z.Ö.) and FV30300 (Z.W.). We acknowledge the provision of facilities and technical support by Aalto University Nanomicroscopy Center (Aalto-NMC). We thank Dr. S. Hietala for useful discussion on rheology. Part of this work is also carried out under the framework of Centre of Excellence in Molecular Engineering of Biosynthetic Hybrid Materials (HYBER 2014-2019) and Photonics Research and Innovation (PRIEN) flagship program. Z.Ö. thanks Erasmus+ program of the EU for funding her study visit to the Aalto University, Finland. L.R. thanks the Czech Science Foundation for the grant No. 19-01383S.

SYNOPSIS

For the Table of Contents Only:

Self-assembly of strategically designed oleanolic acid-triazole-spermine conjugates are reported, showing that these amphiphiles undergo spontaneous gelation in organic solvents displaying a mixed self-healing and thixotropic properties.
